AI-Based Recognition of Medicinal Plants and Their Benefits Using Deep Learning

Pranjali Uddhav Pawar[1], Prof. Dhanashri Abhang[2], Sakshi Shahaji Patil[3]
[1, 3]MCA Student (Semester III), [2]Research Guide / Professor, JSPM's Narhe Technical Campus Pune, affiliated to Savitribai Phule Pune University, Pune, India,2026

Abstract: ***Traditional healthcare systems rely heavily on Medicinal plants, but non-medical professionals face difficulties in accurately identifying species based on the appearance of their leaves. The paper suggests an artificial intelligence-based system that can recognize medicinal plants by analyzing leaf images and presents traditionally reported benefits. Combining OpenCV-based preprocessing for images, Convolutional Neural Network (CNN) classification utilizing TensorFlow and Keras, and an SQLite database with plant information is utilized by the system. Users can upload an image and view the predicted name of the plant along with related information using a Tkinter graphical interface. A workflow is proposed that involves preparing the dataset, improving its image quality, training models, creating predictions and then testing it against other databases with various criteria such as accuracy, precision, recall, F1-score or loss. While this paper provides a conceptual design and proposed evaluation approach, the implementation results are not made public. This system is intended to be an educational tool and for preliminary identification purposes, and the accuracy of automated predictions must be confirmed by qualified botany professionals. The index encompasses Ayurveda, plant identification, medicinal plants, deep learning, convolutional neural network, and image recognition.***

Index Terms: ***Medicinal plants, image recognition, deep learning, convolutional neural network, image processing, Ayurveda, plant identification.***

I. INTRODUCTION

Many of these plants have significance within traditional medicine. Accurate identification of medicinal plants is important to ensure appropriate and safe usage of the plant. Mistaken identification of different species of plants may cause inappropriate or unsafe usage of plants. Medicinal plants can be difficult to identify, and usually relies on experts within botany, herbal medicine and other fields. By taking an image of a plant, features can be extracted to identify the plant. For image classification problems, common methods involve Convolutional Neural Networks (CNNs) to extract patterns from training images. This project aims to create an application allowing users to perform basic identification of selected medicinal plants using images of their leaves. The application will contain image preprocessing, classification using a CNN created using Tensorflow and Keras, a database containing information about the plants, and a basic GUI. The application will allow users to gain an initial identification, and easily gain knowledge about selected medicinal plants and their traditional uses.

A. Limitations in Existing Approaches

It can be time-consuming to identify plants manually. It may also be difficult to identify plants if the user has little experience. With traditional image processing, identification may be performed using pre-defined features. However, this can be affected by lighting, background and camera position. Using deep learning methods may improve the identification by allowing more complex patterns to be learnt. However, the performance of the model depends on the quality and variety of labelled images, and available computing power. Leaves from different species may be very similar, meaning careful consideration should be given to predicted identifications, and the traditional uses associated within the database.

B. Research Objectives

Objects of the work include: creating a classification workflow for plant images; collecting and analyzing medicinal plant leaves datasets; training/evaluating images using CMOS, CNN algorithms; connecting forecasting to underlying plant-information databases; developing UI design; and testing the model against industry-standard classification metrics.

C. Scope and Safety Considerations

This application is only intended to be used for gaining knowledge and basic identification of plants. It cannot be used to diagnose medical conditions, nor suggest treatments. Plants should not be consumed, or applied to the body, based solely upon this application. If results are unclear, or if the plant is going to be used, the identity of the plant should be checked by a qualified expert.

II. RELATED LITERATURE AND THEORETICAL BACKGROUND

Manually engineered shape, colour, and texture features were employed by conventional classifiers in early image-recognition systems. Hierarchical image features are learned by deep-learning techniques directly from data. The use of CNN architectures for image classification was demonstrated by AlexNet, VGG, and ResNet. Transfer learning can also be useful in managing limited plant datasets. This is a result of transfer learning. The proposed study utilizes these fundamental methods for identifying medicinal leaves and interconnects predictions with an informational database.'

III. SYSTEM METHODOLOGY AND ARCHITECTURE

A. Layered Architecture

Layer	Function	Suggested tools
Data input	Leaf image upload and dataset inputs	Camera / file upload
Image preprocessing	Resize, normalize, filter and augment	OpenCV
AI analysis	CNN feature extraction and classification	TensorFlow / Keras
Prediction processing	Class label and confidence handling	Python
Database	Plant names, uses, benefits and parts used	SQLite
Application interface	Upload, preview and prediction display	Tkinter
Evaluation	Metrics and confusion matrix	Python / scikit-learn

End-to-end workflow: the user uploads a leaf image; preprocessing resizes and normalizes it; the CNN predicts a plant class and confidence score; the predicted class is used to retrieve a database record; and the interface displays the plant name and informational content. Low-confidence predictions should be flagged rather than presented as certain.

B. Image Processing and Classification

Input dimensions are fixed, such as 224 221 pixels; the images are then normalized to some value within its (the input) range of 0–1, with an option for filtering optionally in order to reduce noise. Data can be enhanced through the use of rotation, flipping, zooming, and brightness variation. A CNN may include layers of convolution and max-pooling, then be flattened, fully connected layers with a dropout, and filtered to softmax output. The use of Adam and categorical cross-entropy in training can be combined with a validation split for performance evaluation.

C. Database and User Interface

The SQLite database contains information on common names, scientific names and commonly reported uses, as well as benefits or plant parts. Its lookup key is the class that has been predicted. Image uploading, previewing and prediction, as well as displaying the recovered data via the Tkinter interface are all supported by the user interface.

D. Evaluation Protocol

Separating the dataset into training, validation, and testing partitions, along with separating the source or specimen to minimize leakage. Using accuracy, precision, recall (conclusion criteria), the F1-score, loss and confusion matrix, one can evaluate performance. The number of images per species and dataset conditions must be recorded..

IV. PROPOSED EXPERIMENTAL DESIGN

A. Dataset Preparation

To gather images of plants, it is important to use reliable and documented sources that are organized by species. Diverse backgrounds, lighting options and positions are essential to include in the dataset. Verification of species labels based on botanical references, along with scrutiny of licensing and annotation quality.[B].

B. Proposed Model Configurations

Comparisons between a baseline image classifier, cyclic CNN from scratch, and transfer-learning model are possible in this study. The same test partition should be used for all configurations, and model selection should rely on training or validation data.

C. Planned Evaluation Metrics

Metric	Definition
Accuracy	(TP + TN) / (TP + TN + FP + FN)
Precision	TP / (TP + FP)
Recall	TP / (TP + FN)
F1-score	2 × Precision × Recall / (Precision + Recall)
Loss	Training and validation loss values

V. EXAMPLES OF MEDICINAL PLANTS

The examples below illustrate the kinds of leaf images and informational records the system is designed to handle. Benefits are traditionally reported and are not medical advice.

Plant	Scientific name	Leaf features	Traditionally reported uses	Image
Tulsi (Holy Basil)	Ocimum tenuiflorum	Small oval leaves, slightly serrated, aromatic	Traditionally used for cough, cold and respiratory complaints; general wellness support	
Neem	Azadirachta indica	Compound leaves with narrow serrated leaflets	Traditional skin and dental care; antimicrobial applications	
Aloe vera	Aloe barbadensis miller	Thick, fleshy lance-shaped leaves with spiny margins	Gel traditionally used topically for skin soothing and minor burns	
Turmeric	Curcuma longa	Large lanceolate leaves with prominent midrib	Rhizome traditionally used in food and traditional preparations	
Ashwagandha	Withania somnifera	Simple ovate, slightly hairy leaves	Traditionally used as an adaptogen	
Amla	Phyllanthus emblica	Small leaflets arranged along a twig	Fruit traditionally used as a tonic and in digestive preparations

A. Worked Example: Tulsi

A Tulsi leaf image is uploaded by a user. A class named Ocimum tenuiflorum is predicted by the CNN with a confidence score, while the preprocessing module prepares the image. The system retrieves the corresponding SQLite record and exhibits both common name, scientific name (such as MongoDB table), and traditional information. It is important to make the interface clearly state that the result is informational and not medical advice.

B. Challenging Look-Alike Cases

Different species with similar leaf shapes, texture or margins may be difficult to identify, including varieties of basil and other related plants. A diverse dataset, confidence threshold, and expert verification are crucial safeguards.. 1.
Recognition may be difficult among species with similar leaf shape, texture or margins, including varieties of basil and other related plants. A varied dataset, confidence threshold and expert verification are important safeguards.

VI. EXPECTED OUTCOMES AND DISCUSSION

The proposed system is expected to identify various classes of medicinal plants using images of leaves, and retrieve the associated information from the leaf. A user interface is designed to facilitate the identification of preliminary tests for non-experts. These outcomes are foreseeable and not quantifiable.

A. Model Comparison

Approach	Expected strength	Expected limitation
Image preprocessing + baseline	Simple, useful benchmark	Handcrafted or limited features may not generalize
CNN	Learns visual features from images	Needs varied labelled data and computation
Transfer learning	May benefit from pretrained feature representations	Results depend on model, dataset and fine-tuning

The dataset and evaluation conditions will determine whether these expectations hold. Confusion between look-alike species, image quality and class imbalance should be discussed using actual test results after implementation.

VII. LIMITATIONS AND THREATS TO VALIDITY

This paper presents a suggested system without any experimental verification. Image quality, leaf damage, lighting, background, and similar species may have an impact on recognition.. In certain instances, identification solely of the leaf may not suffice.' Database information needs to be inspected and revised; traditional uses should not be presented as proven clinical outcomes.

VIII. FUTURE SCOPE

Future work could involve the creation of a more diverse dataset, real-time camera identification, cellular app functionality, multilingual output, and additional plant components such as flowers, fruits, or bark. Additionally, there are no currently available projects. Verified safety details, warnings and interactions may be included in the database after a thorough source review.

IX. CONCLUSION

A system that employs AI-based medicinal plant recognition and combines image preprocessing, CNN classification, a database of medicinal information, and an intuitive user interface is presented in this paper. The design is intended to simplify the process of identifying plants before they grow in the wild and facilitate the recording of traditional knowledge for educational purposes. Authentic deployment requires a diverse dataset, rigorous testing methods, expert verification, and logical presentation of safety limitations.
