BER Analysis of the Effect of Group Delay in RRC Filter with Marc Technique

Raj Kumar Gupta[1], Sudhanshu Singh[1], Sangeeta Shekhawat[1]

[1,2,3,4] *Assistant Professor, Department of ECE, Amity University Rajasthan, Jaipur India*

Abstract: Wide Code Division Multiple Access (WCDMA) is a third generation (3G) wireless based communication system that has higher data rates, high bandwidth and support multimedia communication capabilities for global mobile communications but the performance of WCDMA is debauched with different factors like noise, fading, scattering, interference .This paper investigates the effect of group delay in root raised cosine filter for wideband code division multiple access and bit error rate performance is analyzed with single input single output antenna system and single input multiple outputs antenna system using maximum ratio combining diversity technique by varying the group delay for quadrature phase shift keying(QPSK) and binary phase shift keying(BPSK).
Keywords: WCDMA; root raised cosine filter; group delay; Antenna diversity; Maximum ratio combining.

I. INTRODUCTION

In wireless communication system WCDMA is a technology which is based on the direct sequence spread spectrum transmission scheme, where user information bits are spread over a wide bandwidth. WCDMA uses very high bit rate upto 2 Mbps. In order to support very high bit rates variable spreading factor and multicode connection is used. WCDMA uses chip rate of 3.84 Mcps and a carrier bandwidth of 5MHz [1][2]**.** When a signal is transmitted from source to destination through the channel, there are some factors which degenerate the performance of signal and these factors are scattering, noise, fading, path loss and interference. In all these factors fading is very unfavorable factor which attenuates the signal strength .One of the most effective techniques to alleviate the effects of fading is diversity combining technique. In this technique: if one signal path experience a intense fade at a particular point of time, there is a possibility to have a strong signal in another path [3]. In this technique receiver uses multiple copies of the same information signal which are transmitted over communication channels. Hemalatha et.al [4] analyzed diversity in CDMA based broadband wireless system and found that the diversity CDMA system with multiple antennas at the transmitter and receiver results better SNR and trimming in the fading and interference. In communication system pulse shaping filter is used to generate band limited channels and reduce inter symbol interference (ISI) arising from multi path signal reflections [5]. The work in the present paper analyzed the performance of SISO and SIMO using MRC technique by varying the group delay (D) of root raised cosine filter in WCDMA system.

The next Section describes the square root raised cosine filter. The maximum ratio combining (MRC) diversity scheme is presented in Section 3. The simulation results and discussion is presented in the Section 4. The last section concludes the paper and presents the future work.

II. SQUARE ROOT RAISED COSINE FILTER

If channels are too narrow, the symbols will be too wide, hence at sampling points there will be signal of the previous and next symbols. This is called Inter-symbol Interference (ISI).One possible solution is to use an Ideal Low Pass Filter (ILPF) to remove ISI and for Narrow bandwidth channel. But it has some problems that it is physically unrealizable and difficult to approximate. One of the solutions is used Raised Cosine (RC) Filters. It is shown by Nyquist that if the frequency characteristic has odd symmetry at the cutoff frequency, the impulse response will have zeros at uniformly spaced intervals. By using RC filter effects of jitter can be minimized and it is much simpler to attain.

One way to achieving square root raised cosine filter is to take square root of the raised cosine filter in frequency domain and use this new filter in the Tx and Rx. This is the so called Root Raised Cosine filter.

The ideal root raised cosine filter, frequency response consists of unity gain at low frequencies and total attenuation at the high frequencies, the square root of raised cosine function in the middle.   The width of the middle frequencies is defined by roll off factor constant α. Group delay of filter is defined by initial response and its peak response. The group delay plays a crucial role in pulse shaping digital finite impulse response filter. The value of group delay should be minimal for efficient performance of digital

pulse shaping filter. The group delay influences the size of output as well as order of filter. For minimizing the filter complexity, filter length or number of taps should be minimum as far as possible. There is tradeoff between group delay (D) and interpolation factor (M) for better performance of pulse shaping filter for WCDMA based wireless communication system. So group delay should be minimum for reducing the filter complexity.

$$N = D*M$$

(1)

N= filter taps
D= group delay
M= interpolation factor

The spectrum of square root raised cosine (SRRC) spectrum is given in following equation

$$SRRC(t) = \frac{\sin(\pi \frac{t}{T_c}(1-\alpha)) + 4\alpha \frac{t}{T_c}\cos(\pi \frac{t}{T_c}(1+\alpha))}{\pi \frac{t}{T_c}(1 - (4\alpha \frac{t}{T_c})^2)}$$

(2)

Where Tc is the inverse of chip rate.
α= Roll off factor.

III.   MAXIMUM RATIO COMBINING

The diversity approach is the solution to improve the performance of system which is affected by fading. In this approach if one signal path experience a intense fade at a particular point of time, there is a possibility to have a strong signal in another path. There are so many diversity approaches such as frequency diversity, time diversity, Antenna diversity and polarization diversity. But one of the most important techniques is antenna diversity.   In this approach multiple antennas are placed at the transmitter and/or the receiver [7]. Antenna diversity techniques use some combining approaches like selection combining, maximum ratio combining, and equal gain combining. The antenna diversity approach for single input single output (SISO) and single input multiple outputs (SIMO) are presented below in Fig.2 and Fig.3.

Fig.2 Single Input Single Output Antenna System (SISO)

Fig.3 Single Input Multiple Outputs Antenna System (SIMO)

In maximum ratio combining (MRC) approach, all the branches are used concurrently. Each branch signal is weighted with a gain factor which is proportional to its own signal to noise ratio (SNR). After that, co-phasing and addition operation will be performed. [8]. Fig.4 shows the configuration for a two-branch diversity system. Both the branches are weighted by their respective signal-to-noise ratio and then all the branches are co-phased and added to get the maximum diversity gain. The added signals are used as a received signal and connected to the demodulator [9].
Fig.4   Block diagram of a maximum ratio combining approach

The inputs to the maximum ratio combiner (Fig.4) are   both rayleigh distributed signals (with envelopes r_1 and r_2) with additive independent noise voltage sources n_1 and n_2. n_1 and n_2 are zero mean white gaussian random variables with a variance of N; the input voltage signal-to-noise ratios are

$$SNR_{P_{1,2}} = \frac{r_{1,2}^2}{N} \qquad (3)$$

$$SNR_{V_{1,2}} = \sqrt{SNR_{P_{1,2}}} = \frac{r_{1,2}}{\sqrt{N}} \qquad (4)$$

The SNR after maximum ratio combining (MRC) requires the evaluation of the instantaneous signal power and noise power. The amplitude of the signal of interest after MRC at a give time t_0, $V_{S,M}(t_0)$, can be evaluated by multiplying the received signal enveloper r_1 and r_2, at t_0, by their instantaneous voltage to noise power ratios which when summed gives.

$$V_{S,M}(t_0) = r_1(t_0)\left(\frac{r_1(t_0)}{N}\right) + r_2(t_0)\left(\frac{r_2(t_0)}{N}\right) = \frac{r_1(t_0)^2 + r_2(t_0)^2}{N} \qquad (5)$$

$$P_{S,M}(t_0) = V_{S,M}(t_0)^2 = \left(\frac{r_1(t_0)^2 + r_2(t_0)^2}{N}\right)^2 \qquad (6)$$

The noise component after MRC at t_0, $V_{N,M}(t_0)$, is also multiplied by the gains in both branches and evaluates after co-phasing and branch addition to

$$V_{N,M}(t_0) = n_1\left(\frac{r_1(t_0)}{N}\right) + n_2\left(\frac{r_2(t_0)}{N}\right) = \frac{n_1 r_1(t_0) + n_2 r_2(t_0)}{N} \qquad (7)$$

The noise power is given by

$$P_N = E[n_x^2] = \int_{-\infty}^{\infty} n_x^2 f_{N_x}(n_x) dn_x = N_x$$

$$P_{N,M}(t_0) = [V_{N,M}(t_0)^2] = E\left[\frac{n_1^2 r_1(t_0)^2}{N^2} + \frac{2n_1 n_2 r_1(t_0) r_2(t_0)}{N^2} + \frac{n_2^2 r_2(t_0)^2}{N^2}\right]$$

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

The middle term evaluates to zero since each noise source is independent of all other signals and has a mean of zero.

$$P_{N,M}(t_0) = E\left[\frac{n_1^2 r_1(t_0)^2}{N^2}\right] + E\left[\frac{n_2^2 r_2(t_0)^2}{N^2}\right]$$

$$P_{N,M}(t_0) = \frac{r_1(t_0)^2}{N^2}E[n_1^2] + \frac{r_2(t_0)^2}{N^2}E[n_2^2] = \frac{r_1(t_0)^2 + r_2(t_0)^2}{N}$$

$$SNR_{P_M}(t_0) = \frac{Power_{Signal}}{Power_{Noise}} = \frac{P_{S,M}(t_0)}{P_{N,M}(t_0)} = \frac{V_{S,M}(t_0)^2}{E[V_{N,M}(t_0)^2]}$$

$$SNR_{P_M}(t_0) = \frac{r_1(t_0)^2 + r_2(t_0)^2}{N} = \frac{1}{N}\left(r_1(t_0)^2 + r_2(t_0)^2\right)$$

(8)

$$MGC\,Output(dB) = SNR1 + SNR2$$

$$SNR_{V_M}(t_0) = \sqrt{SNR_{P_M}(t_0)} = \sqrt{\frac{r_1(t_0)^2 + r_2(t_0)^2}{N}} = \frac{1}{\sqrt{N}}\sqrt{r_1(t_0)^2 + r_2(t_0)^2}$$

$$SNR_{P_M}\Big|_{N=1} = r_1^2 + r_2^2$$

(9)

$$SNR_{V_M}\Big|_{N=1} = \sqrt{r_1^2 + r_2^2}$$

(10)

IV. SIMULATION RESULTS AND DISCUSSION

Simulation results of varying group delay in RRC filter with maximum ration combining approach for WCDMA system are analyzed in this section. In this approach we use two antennas (nRx1 and nRx2) at the receiver side with different values of group delay (D) in root raised cosine (RRC) filter. The WCDMA system is simulated in MATLAB and To analysis the result of group delay the other factors such as interpolation factor (M) and roll of factor (α) are fixed at M=5 and α=0.22 in RRC filter. The performance of the MRC antenna diversity scheme is analyzed at different values of group delay (D) in RRC filter. The simulation analysis has been carried out using QPSK and BPSK modulation techniques in two cases. Case 1 based on QPSK for MRC and case 2 based on BPSK for MRC.

*A. Case-1* BER analysis of QPSK by varying group delay (D)

Fig 5 (D=2)

Fig 9 (D=10)

The BER v/s Eb/No relationship for the WCDMA system with nRx= 1,2 is shown in Fig. 5 to Fig.9 with QPSK modulation scheme using MRC technique. As can be seen from Fig.5 in case of nRx=2,initially the BER obtained around 0.4205 and at higher value of Eb/No, the achievable BER decreases around 0.0167 for 7 dB Eb/No at D=2. At D=3 initially the BER obtained around 0.4164 and at higher value of Eb/No, the achievable BER decreases around 0.0135 for 7 dB Eb/No shown in Fig.6 for nRx=2. From Fig.7 initially the BER obtained around 0.4158 and at higher value of Eb/No, the achievable BER decreases around 0.0100 for 7 dB Eb/No at D=5. At D=7 initially the BER obtained around 0.4194 and at higher value of Eb/No, the achievable BER decreases around 0.0108 for 7 dB Eb/No shown in Fig.8. From Fig.9 initially the BER obtained around 0.4209 and at higher value of Eb/No, the achievable BER decreases around 0.0129 for 7 dB Eb/No at D=10.

It is observed from the simulation that the BER is gradually decrease when group delay varying from 2 to 5 When group delay varying from 5 to 10, BER is increased again. The optimum value of group delay was found to be 5, at which both SISO and SIMO WCDMA system gave best performance [10].

B.   *Case-2* BER analysis of BPSK by varying group delay (D)

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

Fig 14 (D=10)

The BER v/s Eb/No relationship for the WCDMA system with nRx= 1,2 is shown in Fig. 10 to Fig.14 with BPSK modulation scheme using MRC technique. As can be seen from Fig.10 in case of nRx=2,initially the BER obtained around 0.0714 and at higher value of Eb/No, the achievable BER decreases around 0.0002 for 7 dB Eb/No at D=2. At D=3 initially the BER obtained around 0.0626 and at higher value of Eb/No, the achievable BER decreases around 0.0001 for 7 dB Eb/No shown in Fig.11 for nRx=2. From Fig.12 initially the BER obtained around 0.0564 and at higher value of Eb/No, the achievable BER decreases around 0 for 7 dB Eb/No at D=5. At D=7 initially the BER obtained around 0.0573 and at higher value of Eb/No, the achievable BER decreases around 0.0001 for 7 dB Eb/No shown in Fig.13. From Fig.14 initially the BER obtained around 0.0614 and at higher value of Eb/No, the achievable BER decreases around 0.0003 for 7 dB Eb/No at D=10.

It is observed from the simulation that the BER is gradually decrease when group delay varying from 2 to 5 When group delay varying from 5 to 10, BER is increased again. The optimum value of group delay was found to be 5, at which both SISO and SIMO WCDMA system gave best performance [11].

V.   CONCLUSION

The work in this paper analyzed the joint effect of maximum ratio combining diversity approach with root raised cosine (RRC) filter to reduce the effect of inter symbol interference , inter-intra cell interference and fading. The increasing delay in RRC filter increases the complexity in the system and decreases the BER performance for both SISO and SIMO WCDMA system. It was observed from the simulation result that the SIMO system gave better performance in comparison to the SISO system. Results also conclude that BPSK modulation technique is better compare to QPSK for SISO and SIMO. In future work the same analysis will be carried out for MIMO system and implement on FPGA.
