## II. LITERATURE SURVEY

A. *Wang, J., Gan, Y., Liang, J., Tan, M., & Li, Y. (2019). Sensitivity analysis of factors influencing a heat pipe-based thermal management system for a battery module with cylindrical cells. Applied Thermal Engineering, 151(February), 475–485. https://doi.org/10.1016/j.applthermaleng.2019.02.036* [1]

The research objective of this paper is to perform a sensitivity analysis of the factors influencing the thermal performance of a heat pipe-based thermal management system for a battery module with cylindrical cells. The study aims to identify the most sensitive factors affecting the thermal performance of the battery module and to optimize the design of the thermal management system to enhance its cooling efficiency. The result of the research indicates that the height of the conduction element has the most significant effect on the thermal performance of the heat pipe-based thermal management system for a battery module with cylindrical cells. This means that the height of the conduction element is the most critical factor that affects the cooling efficiency of the battery module. The study also found that the circumference angle between the battery and conduction element has a significant effect on the thermal performance, while the battery spacing and the thickness of the conduction element have minimal effects. [1]

The conclusion of the research paper is that the structural parameters of a battery thermal management system (BTMS) have a significant effect on its thermal performance. The study used computational fluid dynamics (CFD) and an orthogonal numerical test to identify the most sensitive factors affecting the cooling efficiency of the BTMS. The results of the study showed that the height of the conduction element has the most sensitive effect on the battery module, followed by the circumference angle between the battery and conduction element. The battery spacing and the thickness of the conduction element have minimal effects on the thermal performance. The study also optimized the design of the thermal management system based on the optimal parameters, resulting in the best thermal performance with a maximum temperature of 27.62 °C and a temperature difference of 1.08 °C. The research concludes that structural parameters have a significant effect on the thermal performance of a battery thermal management system and that optimizing the design of the BTMS can enhance its cooling efficiency and prevent battery degradation and failure. The study provides valuable insights into the factors that affect the thermal performance of a BTMS and can help in the development of more efficient and reliable battery systems.

B. *Weiss, L.; Amara, M.; Ménézo, C. Impact of radiative-heat transfer on photovoltaic module temperature. Prog. Photovolt. Res.Appl. 2016, 24, 12–27.* [2]

The objective of this paper is to present a detailed analysis of the optical, thermal, and electrical behavior of crystalline silicon solar modules, and to demonstrate the impact of radiative-heat transfer on photovoltaic module temperature. The study aims to predict the power output of the PV module depending on the environmental conditions and to evaluate the factors that impact the performance ratio of the module in real conditions. The ultimate goal is to optimize the energy production of a PV module. [2]

This study provides a detailed analysis of the optical, thermal, and electrical behavior of crystalline silicon solar modules, and the impact of radiative-heat transfer on photovoltaic module temperature. The authors build a complete multi-physics model that can describe the behaviors of a PV module depending on the environmental conditions, treating radiation heat transfer in participating media. The study aims to predict the power output of the PV module depending on the environmental conditions and to evaluate the factors that impact the performance ratio of the module in real conditions. The study demonstrates the limits of commonly used modeling and opens new possibilities for improving the PV module yield and design strategy. The results show that the lower homogeneity of the temperature distribution in the case of the RAD method may produce some error in the evaluation of the power generation for highly variation environmental conditions. These results have been obtained for the quite stable conditions and gradual climate evolution for a clear sky day. Further comparison should be conducted for more abrupt irradiance changes (cloudy day) to demonstrate the robustness and accuracy of the model. The model could also be confronted to local temperature evolution that could be measured at the level of the PV module (surface, inside, etc).

The paper presents a compact thermal model for bended heat pipes and an efficient thermal simulator for smartphones. The goal is to simulate the thermal dissipation from heat sources through many material blocks that have different equivalent thermal conductances to the outside enclosure. The paper also details the automatic heat pipe routing flow and proposes a thermal-driven routing algorithm for optimizing the design of bended heat pipe. The proposed heat pipe routing algorithm can reduce at least 10.86% of the maximum temperatures for application processors.

The paper also establishes a compact thermal model for bended heat pipes to construct an efficient thermal simulator for smartphones. The efficiency and accuracy of the developed thermal simulator are validated by the commercial tool, ANSYS Fluent. [3]

The paper presents a compact thermal model for bended heat pipes and an efficient thermal simulator for smartphones. The thermal simulation with bended heat pipe thermal model can achieve at least three orders of magnitude speedup with only 3.58% maximum error for all chips. The proposed heat pipe routing algorithm can reduce at least 10.86% of the maximum temperatures for application processors. The rest of the paper is organized as follows: Section II presents the thermal simulator for smartphones with a compact model of bended heat pipe. Section III details the automatic heat pipe routing flow. Section IV gives the experimental results. Finally, Section V concludes this work.

The limitation of this paper is that it focuses only on the thermal modeling and design of smartphones with heat pipe cooling technique. It does not cover other cooling techniques or other aspects of smartphone design. Additionally, while the paper presents a compact thermal model for bended heat pipes and an efficient thermal simulator for smartphones, it does not provide a comprehensive comparison with other existing thermal simulation tools. This paper presents a numerical and experimental study on the effect of solid particles flow on heat pipe performance. The study used Ansys fluent 18.0 as a computer program and a 3D steady-state model to understand the temperature distribution inside the evaporator and condenser part domain.

The study also used a 2D transient model to study particle behavior and streamline. The experimental setup included three heat pipes, a wooden box, data acquisition, electrical heater, cyclone, and air blower. The results showed that increasing particle bed height and velocity increased heat transfer coefficient and heat gain. The study also found that fluidization, which is the butting of small particles in the domain and moving them by an external force, can significantly increase the domain heat transfer coefficient. The study showed that increasing Reynolds number increased the Nusselt number. The study also found that the third upward pipe is the hottest one compared to the previous downward pipes.

This paper presents a numerical and experimental study on the effect of solid particles flow on heat pipe performance. The study used Ansys fluent 18.0 as a computer program and a 3D model with steady state was studied to know the temperature distributed inside the evaporator and condenser part domain.

The study also used a 2D model with transient. The result showed an enhancement in Nusselt number by 58% when the velocity was 1.377 m/s and particle bed height was 5 cm compared with the first state. The pressure drop was measured not to exceed 42%. The study used the Eulerian-Eulerian model, and the turbulence model used was the RNG model. The study showed that increasing heat transfer coefficient by 89% when increased particle bed height from 0 to 5 cm. The study also showed that the third pipe is the hottest one if compared with the previous downward pipes.

The relationship between Nusselt and Reynolds number was also studied, and it was observed that with increased Reynolds number, Nusselt number was increased due to increasing heat transfer coefficient.

The study conducted a numerical and experimental investigation on the effect of solid particles flow on heat pipe performance. Ansys fluent 18.0 was used as a computer program, and a 3D steady-state model was studied to know the temperature distribution inside the evaporator and condenser part domain. A 2D transient model was also studied to observe particle behavior and streamline. The study used particles of 105μm diameter and experimental measuring properties set with a height range of (2.5 to 5) cm inside the evaporator part from the box, and velocity with a range of (0.8739 to 1.377) m/s was taken into consideration. The results showed an enhancement in Nusselt number by 58% when the velocity was 1.377 m/s and particle bed height was 5 cm compared to the first state. The pressure drop was measured within an acceptable range and did not exceed 42%.

The research has some limitations, but the measured data uncertainties were taken into account, and their values were acceptable. The uncertainty of the experiments was calculated by considering the divergence in values, and the tests were performed three times, and the mean temperature values were utilized for analysis. The accuracy of the thermocouples and cold fluid flow meter used were ± 0.5 °C and ± 0.15 lpm, respectively, while the wattmeter's accuracy was ± 0.9 W. Based on Eq. the experiments' uncertainty lied within ± 1.785%. [4]

E. *Pawar, V. R., & Sobhansarbandi, S. (2020). CFD modeling of a thermal energy storage based heat pipe evacuated tube solar collector. Journal of Energy Storage, 30(January), 101528.* [5]

The paper discusses the computational fluid dynamics (CFD) modeling of a heat pipe evacuated tube solar collector (HPETC) with and without the integration of phase change materials (PCMs). The simulation results show an acceptable agreement with the experimental data with an average deviation of 4.80% and 2.04% for phase-I and phase-II, respectively. The result from this study can be a benchmark for further optimization of HPETCs in thermal energy storage systems.

This research focuses on the computational fluid dynamics (CFD) modeling of a heat pipe evacuated tube solar collector (HPETC) with and without the integration of phase change materials (PCMs). The study aims to optimize the performance of HPETCs in thermal energy storage systems. The HPETC consists of a heat pipe that is located inside the inner tube, and the heat pipe contains a heat transfer fluid that transfers the heat to the system's manifold. The selected type of PCM is Tritriacontane paraffin with a melting point of 72 ∘ C. The simulation results show an acceptable agreement with the experimental data with an average deviation of 4.80% and 2.04% for phase-I and phase-II, respectively. The result from this study can be a benchmark for further optimization of HPETCs in thermal energy storage systems.

The research investigated the thermal performance of a heat pipe evacuated tube solar collector (HPETC) with and without the integration of phase change materials (PCMs) using computational fluid dynamics (CFD) modeling. The results showed that the HPETC integrated with PCM had an efficiency improvement of 26% for normal operation and 66% for stagnation mode compared to the conventional HPETC without PCM. The selected type of PCM was Tritriacontane paraffin with a melting point of 72 °C. The simulation results showed an acceptable agreement with the experimental data with an average deviation of 4.80%. [5]

One limitation of the research is that the thermal losses from the end face of the collector were neglected in the simulation analysis, which may cause a slight variation between the simulation and experimental results. However, this deviation percentage is acceptable and in agreement with previously published work.
