[6]Assistant Professor Department of Information Technology, K.D.K. College Of Engineering, Nagpur, India

Abstract: In this paper we have proposed face recognition door lock system using raspberry pi for enhancing security purpose. Implementation of the device is for monitoring whether any unknown person is entering from the door. In order to get accurate and clear picture of an victim we have proposed Haar Cascade method for detecting face. As soon as the person enters near the door, pi camera captures the image of that person and face detection process is done then if it matches with images available in database then the door is unlocked otherwise a message with the picture of a person will be sent to the registered mobile through LAN network. The main motto of this project is to utilization of sensor with the combination of embedded equipment for the door opening systems. The main purpose of this system is to provide best security for home and office by using face recognition technique.

I. INTRODUCTION

Nowadays, as the technology is developing rapidly, facilities for human beings are developing. In day-to-day activities, life of people has become very easier with the implementation of many new technologies. On the other hand, it also produces the major security issues. In general, in order to secure their residence, people make use of CCTV cameras. Images will store in the cloud, so that the action can be taken when any suspicious incident takes place. This type of approach is a passive. But there is a need for an active approach which works on Realtime. This type of approach is nothing but where actions can be taken immediately as soon as a security threat occurs. Hence a smart IOT based face recognition device is the new idea to develop, which recognizes the face of the person near by the door and compares with the uploaded faces stored in the cloud. If image of person is matched with database image, then the door would open and welcomes them. If an unknown person trying to enter, the owner would be alerted automatically by message and mail with an intruder image. To develop this system, we have used Raspberry Pi, Pi camera which will be installed intruder, DC motor to open the door through relay, indicate whether the door is opened or not, the security sector is experiencing diversification. Further modification in the system can be to biometric security system to ensure better security. Biometric security system includes fingerprint-based device was the first biometric locking system. Using the fingerprints of a known person for unlocking the door is main parameter for this system. However, like any other devices, they also have drawbacks. Fingerprints of a person can be duplicated by the victims. This can lead to opening of the door for victims. Finally, research moved to image processing system. This system provides high security.

Figure1. Overall block diagram of automatic door access system using face recognition

This module is used in order to send messages to the registered mobile number. When a person wants to access his locker, initially at the main door of locker and sensor will be placed. This sensor will sense the body temperature of a person who is standing near the door. And then, his/her image will be captured by the camera which is installed at the main gate. This image will be given to the PC where the MATLAB software will compare this image with the authentic images stored in the PC If the person is authentic, then only the door will open otherwise it will remain closed and the alarm will buzz for further action to near the door for recognition of face.

II. LITERATURE REVIEW

In this project we using one camera which is identify an owner of home and open the door in few second. If in home kids or older age's in home need more attention and care that time, we not able to go home that we need someone how take care our love one's but here's problem how go inside the home because face recognition system that time we use alternate option the system well send notification to owner told some stand out of door or the person call owner how to get inside the home by enter OTP.From decades, for science society using of smart home is not a new term. As there is an advance in technology there is a fast increase in the field of home security automation. The control of smart device for automatic door lock system is done using Bluetooth, internet etc. Most of the laptops, tablets, mobiles have built-in adapters which in turn reduce the cost of the system, but it controls within the Bluetooth range not beyond that. The system which is based on SMS technology have only one components i.e. micro controller. Here micro controller is working like bridge between the user, sensors and actuators. By using PCA, Eigen faces are generated by changing the faces available in the database. Distance of the person from door is calculated by Euclidean distance method. If the distance is less, then only it is a recognized face. After that by using module the system generates an alert message to the owner.

A. LBPH Algorithm

Humans' beings perform face recognition every day and practically with zero effort. Although it seems like a very simple task for us, it has proven to be a more complex task for a computer, as it has many variables that can impair the accuracy of the system, for example: illumination variation, low resolution, occlusion, amongst other and more. In computer science, face recognition is basically method of recognizing a person based on their facial image. It has become very famous in last two decades, mainly because of the new methods developed and the high picture quality of the current videos/cameras.

Equations

LBPH (X_c, Y_c) = 's(in-ic) 2" …. (1)

where n runs over the 8 neighbors of the center

pixel, Ic. in are gray-level values in the center pixel and

the function $s(x)$ is defined in (2).

$s(x)= \{1, >=0$ …… (2)

$\{0, x<0$

But there are few limitations to LBPH operator that its small 3x3 matrix method cannot capture the dominant features of large-scale structures. As a result of that, it fails to deal with the texture at different scales, the operator can be extended to use neighborhoods of different.

B. Haar-Cascade Classifier

Detection of object using Haar feature based cascade classifiers is an effective detection of object method proposed by Paul Viola and Michael Jones!". It is a based-on machine learning approach where a cascade function is developed from a lot of positive and negative images. It is then used for detecting objects in other images. Here, we are working with face detection. Initially, the algorithm requires a lot of positive images (images of faces) and negative images (images without faces) to train the classifier accordingly. Then we need to extract features from it. Features are nothing but numerical information extracted from the images that can be used to differentiate one image from another.

Figure 2. Different types of features

Figure 2 shows different Haar features. A simple rectangular Haar like feature can be defined as he differences between the sum of pixels of areas inside the rectangle, which can be at different position and Scale within the original image. A Haar-like feature takes neighboring rectangular regions at a specific location in a detection window, sums up the pixel intensities in each region and calculates the difference between their sums. First, the pixel values inside the black area of rectangular region are added together then the values in the white areas are added. This result is used to differentiate the image sub regions.

An example of this would be the detection of human faces in the images. The areas around the eyes are more darker than the areas on the cheeks!). One example of a Haar like feature for detection of face is therefore a set of two neighboring rectangular areas above the eye and cheek region.

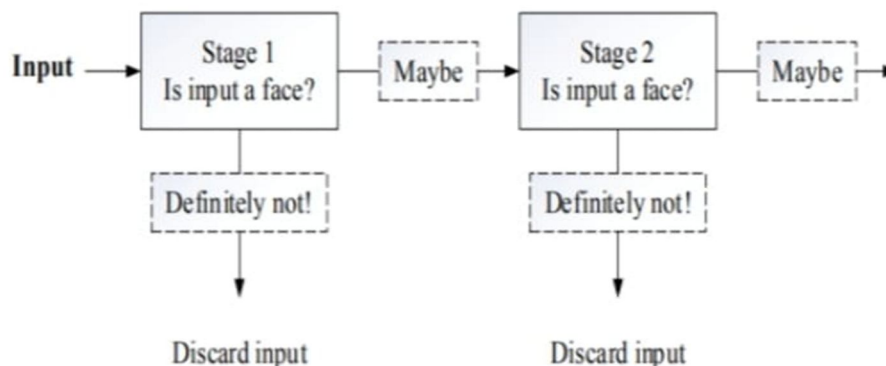

Figure 3. Har-Cascade Classifier

C. Proposed System

After preprocessing like resizing and cropping of images, Haar cascade classifier is used to detect if there is a single face detected or multiple. Figure 4 shows the flowchart for the proposed system of this project. Edge, line, and center surround are the features of Haar which are taken as inputs. By using these cascade features the test of the image is done. The features of Haar are then divided into various stages. Stage by stage the rectangular windows will be tested. The initial stages will having less Haar-like features. If the first stage window fails, then it is to be discarded from the process and the next stages will not be tested. If all the stages successfully completed then only it is considered to be face is detected and then it checks with the images already stored in database of raspberry Pi [9, 12, 13, and 14]. The main advantage of Haar cascade classifiers is to fast detection speed as compared to other classifiers.

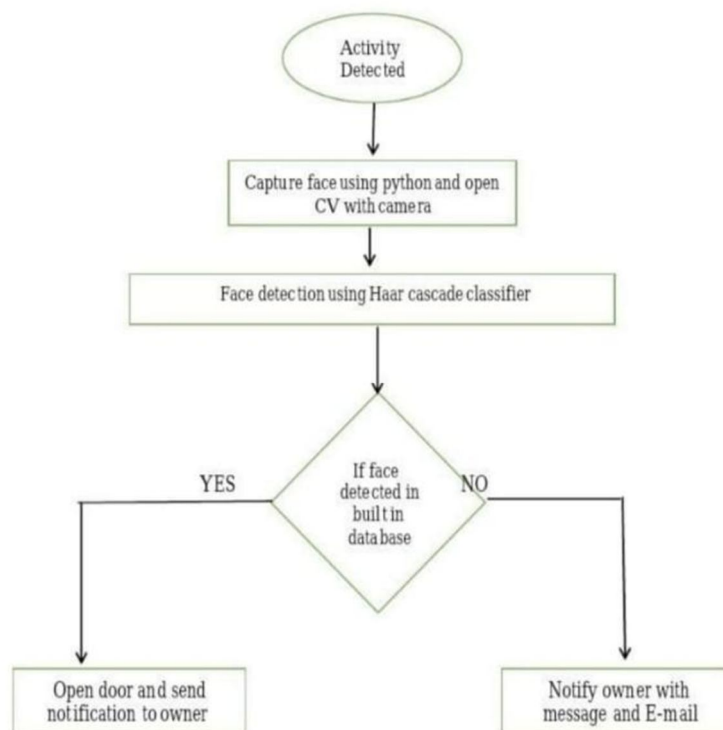

Figure 4. Flowchart of proposed system

D. Methodology

The first task is to collect the data for which we are going to train our classifier. We will write a python code that will take thirty faces of each individual person using OpenCV pre-trained classifier. When the person press the button, the implemented code now called using the camera, system capture the image sequence and compare this image with database. If the image is match , then in application module get the signal to the door. In this project , for face detection and identification we are using machine learning, deep learning and python. For recognise face we using camera and for controlling the locking system weare using nodemcu and all modules integrated through server.

Figure 5. System Block diagram

According to above block diagram shown above, first motion is detected by sensor then the image is captured by camera which is input to the microcontroller, Microcontroller checks whether given input is saved within the database. If yes then the door will open, which is mechanical function done by DC motor. If input image does not match with image in the database then door will remain closed and Buzzer will start beeping and the result will be displayed on the LCD. This project uses system to send notification of an unauthorized person and also to connect hardware with PC it uses serial communication interfacing.

E. Circuit Diagram
The facial recognition circuit diagram.

Figure 6. The facial recognition circuit diagram.

The circuit shows the design of automatic door lock system. The components used are nodemcu, solenoid, adapter . sensor works as a main function. a live body generally emits infrared energy which is sensed by the sensor from considerable distance. This sensing signal is feed to a microcontroller to check the operating range of the sensor, it sends a logical command to open the door. The door automatically closes with affixed time delay. If there is no further movement within the operating range. The interrupt signals are used through limit switches to avoid reverse rotor condition of the motor. The GPIO pins of the Raspberry Pi are use to give an output of 3.3V but the solenoid lock requires 7-12V to operate. Due to this, we will need to use an external power supply and relay to operate the lock. Connect the VCC and GND point of the relay module to 5V and GND of Raspberry Pi. Then connect the signal pin of the relay to the GPIO 26 of the Raspberry Pi. On the other side of the relay module, connect the negative wire form DC power source to the negative point of the solenoid door lock. Connect the positive point from the DC power source to the common of the relay module and then connect normally open from the relay module to positive point of the solenoid door lock. Machine learning algorithm is used to avoid the complexity of calculations, which is inbuilt in Open CV library . Raspberry Pi processes the captured image coordinates with the existing coordinates of the images in the database. If the images matches, then it sends the signals to relay switch through GPIO pins.

III.   HARDWARE DESIGN

A.   I3 Processor

This processor is Developed and manufactured by "Intel" and first introduced and released in 2010 . This core i3 is a dual-core computer processor, Available for use in both desktop and laptop computers . It is one of three types of processors in the "I" series (also called the Intel core family of processors)

Figure 7. I3 Processor

B.   OS Windows XP

Windows XP is a major release of the windows operating system developed by the Microsoft . Itis the direct successors to both windows 2000 for professional users and windows Me for home users, and was released to manufacturing on august 24,2001, and later to retail on October 25,2001.

Figure 8. OS Windows XP

IV.   IOT COMPONENTS

A.   NodeMCU

Figure 9. NodeMCU

NodeMcu is a very low-cost open source IOT device. It initially included firmware which runs on the ESP826 wifi SoC from Espresso if systems , and hardware which was based on the ESP-12. Later, support for the ESP32 32- bit MCU has been added.
B. Solenoid

Figure 10. Solenoid

In electro-magnetic technology, a solenoid is an actuator assembly with a sliding ferro-magnetic Plunger inside the coil. without power, the plunger extends for part of its length outside the coil and applying power pulls the plunger into the coil.

C. Adapter

Figure 11. Adapter

An adapter is the device or system that converts attributes of one electrical device to otherwise incompatible device or system. Some modify power or signal attributes, while others merely adapt the physical form of one connector to another connector.

V.   IMPLEMENTAION

There are single parts in this implementation step. The implementation of face recognition system by using MATLAB.

A. Implementation of Face Detection And Recognition

Matlab2014a is used for coding. In the database folder, 50 different facial part of images for ten persons are used as the training images. While making the folder in the database, the captured images are applied and cropped by face detection module in order to obtain the only facial parts of all images with different directions For instance, five images of a person with different face directions are shown in figure 12.

Figure 12. Five different images for a single face image.

All training images are reshaped and converted into 125x125 gray scale images by using resize and rgb2graymatlab built-in function. Mean centered (or subtracted) images are evaluated by subtracting image from the original training image in the database. The eight vectors corresponding to the covariance matrix define the Eigen faces which looks like ghostly faces. Since 50 training images are used, 50 eigen faces are obtained. Some eigen faces of the training images are shown in figure 13.

Volume 10 Issue II Feb 2022- Available at www.ijraset.com

Figure 13. Some eigen faces of training images

The trained and test images are projected onto the facespace where the eigen faces are the coordinates or dimensions to find their respective euclidian distance. By comparing the euclidian distance of all projected trained images with the projected test image, minimum distance between them which shows similarity to test image is obtained. By using this way, the facial image recognition was done in system.
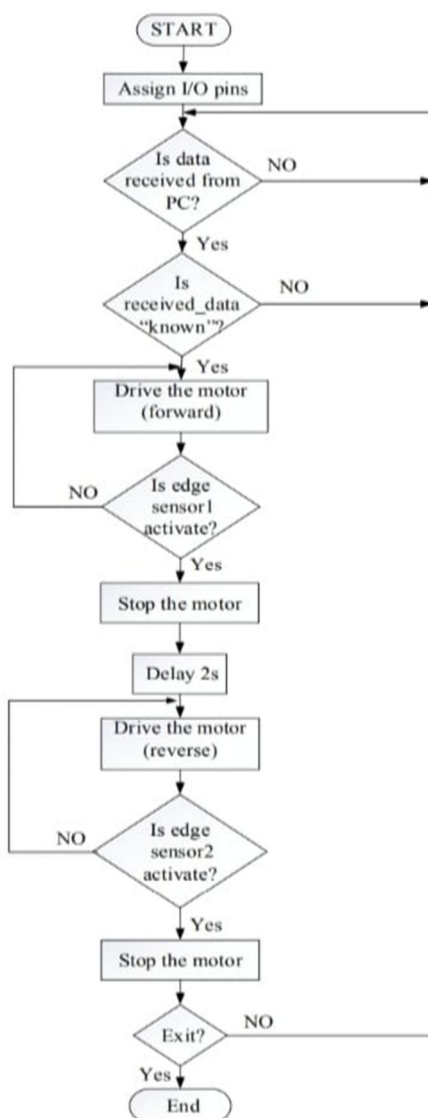

Figure 14. Flowchart for the automatic door and closing system

VI. SIMULATION TESTS AND RESULTS

The overall automatic door access system using face recognition is simulated by using PROTEUS software and MATLAB. VSPE software are used to create a virtual serial port for the communication. A MATLAB GUI is created in order to perform an automatic face recognition and detection. There are two cases in this system. The first is automatic opening of door for the recognized person and the second is ringing the alarm for the unauthenticated person. In this system, input images are taken through the camera continuously until and unless the 'stop camera' button is pressed. Figure 15 shows the MATLAB GUI result when captured face is detected and recognized as authenticated person

Figure 15. Matlab GUI result when captured face is detected and recognised as authenticated person.

When the captured image is recognized as the authenticated person, door motor is rotated in the forward direction until the edge sensor 1 is activated after opening the door. When the sensor 1 is activated, the door motor is stopped. After 2 seconds, door motor is rotated with reverse direction until edge sensor 2 is activated.

Figure 16 and 17 show the simulation result for authenticated person.

Figure 16. Simulation result when the door motor is rotated with forward direction to open door for authenticated person

Figure 17. Simulation result when the door motor is rotated with reverse direction for authenticated person

When the captured image is recognized as unauthenticatedperson, alarm is rung and door is still closed. This simulation result is shown in figure 18.

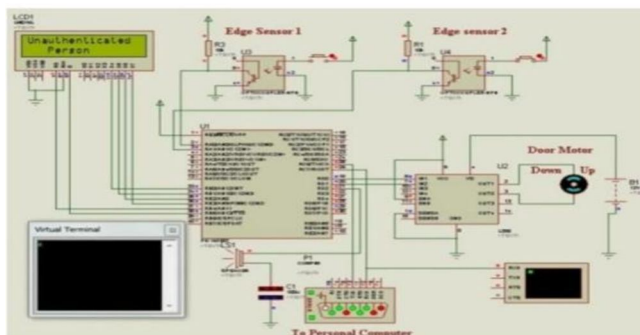

Figure 18. Simulation result for Unauthenticated person

VII.   HARDWARE RESULTS

To perform automatic door access system, personal computer (PC) is connected with the microcontroller via USB to RS232 converter. When no face is detected in front of the webcam, any signal is not sent to the microcontroller. Since microcontroller is not received any signal from PC, the door remains closed. This situation is shown in figure 19.
Figure 19. Hardware test for normal condition when no face detected.

When face is detected, then the name of the recognized person is shown on the detecting box on MATLAB GUI. Once the face is recognized, the door is opened automatically as shown in figure 20.

Figure 20. Hardware test for authenticated person

As shown in figure 21, since there is no facial image of this person in the database folder, this person is recognized as unauthenticated person.

Figure 21. Hardware test for unauthenticated person.

VIII. CONCLUSION

This face recognition system is not 100% accurate, but it works well in good light conditions. The problem with this is it can also detect faces from pictures for instance, someone can unlock the door by showing your picture from his mobile phone. We can resolve this issue by training our own cascade classifier. Face recognition-based door locking has been developed to provide better security. It is user friendly system. The use of Eigen face recognition technique makes this system more secure and faster. This system can be used where high security is required where confidential information and equipment is kept inside. For example, research institutes, banks, forensic Laboratories. This system can also be used for domestic uses for providing securities to home. This project helps to avoid the problem of thefts and frauds by victims. In case of unauthorized person's trying to enter then thsese system alerts authorized person with SMS and at the same time the buzzer beeps to alert people. This is a cost efficient and reliable door locking system.In this paper we have implemented a face recognition door lock system. Recognizing of faces is done by using cascade classifiers, which gets a high accuracy and will store in the database.For this testing, we have used 40 images only. Computervision is used in the IOT. For security purpose, we have implemented real timeface detection by Haar classifier. Thus this system can useful for senior citizens living alone and for mobilized people. Hence the proposed system is practically easy to construct and easy to track the path.
