Advance Sequential Models for Asset Trading: Leveraging LSTM & RNN with Stochastic RSI and MACD Indicators

S.Sreevishnu¹, R.Shyam², Ms.S.Saraswathi.M.E³

^{1,2}Student, ³Asst. Professor, Department of Computer Science Engineering Sathyabama Institute of Science and Technology Chennai, India

Abstract: The goal of stock market prediction is to forecast a company's financial stocks' future worth. The application of machine learning, which creates predictions based on the values of the current stock market indices by training on their prior values, is a recent trend in stock market prediction technologies. Machine learning utilises many models to facilitate accurate and reliable prediction. The study focuses on stock value prediction using regression and LSTM-based machine learning. Considered factors are volume, low, high, open, and closed. We also employ algorithmic trading, which is a technique for automatically executing orders based on pre-programmed trading instructions that take volume, price, and time into account. This kind of trading aims to take advantage of a computer's speed and computational power in comparison to human traders. Algorithmic trading has become more popular in the twenty-first century, prompting traders to respond. According to a 2019 research, 92% of traders use algorithms rather than people. The moving average convergence & divergence and the relative strength index are our primary tools. One technical tool employed in financial market analysis is the relative strength index, or RSI. Charting a stock's historical and present strength or weakness with retail and institutional traders is the goal. Investment banks, mutual funds, pension funds, and hedge funds all utilise it extensively when they need to perform trades. based on the closing prices of a recent trading period, too fast for a human or the market. It is important to distinguish the indicator from relative strength. The RSI measures the speed and size of price changes and is categorised as a momentum oscillator. The rate at which prices rise or fall is known as momentum. The ratio of higher closes to lower closes, where closures are defined as averages of absolute values of price changes, is the relative strength, or RS. The RSI determines momentum by dividing higher closes by overall closes, or stocks with more or stronger positive moves. The RSI is most commonly employed during a 14-day period and is scaled from 0 to 100, with 70 and 30 representing the high and low readings, respectively. Alternately shorter or longer outlooks are associated with shorter or longer time frames. Although they happen less frequently, high and low levels—80 and 20, or 90 and 10—indicate increased momentum. J. Welles Wilder created the relative strength index, which was first published in the June 1978 issue of commodities magazine and in his 1978 book *New concepts in technical trading systems*, and in commodities magazine in the June 1978 issue.

Keywords: Relative strength index, Moving average convergence/divergence, Long short-term memory, Recurrent Neural Network, Application Programming interface.

I. INTRODUCTION

A financial instrument used to symbolise ownership in a corporation that represents a proportionate assertion on its assets and earnings is referred to as a stock or share, often known as a company's equity. A shareholder who owns stock is considered to own a portion of the business, which is equivalent to the number of shares held relative to the total number of outstanding shares of the company. An individual holding 100,000 shares in a business with one million outstanding shares, for instance, would own 10% of the company. The majority of firms have outstanding shares with values in the billions or even millions of dollars. Technical indications are also utilised. A technical indicator in financial technical analysis is a mathematical computation that forecasts the direction of financial markets using historical price, volume, or, in the case of future contracts, open interest data. A key component of technical analysis are technical indicators, which are usually represented as chart patterns with the aim of predicting the direction of the market.

Typically, indicators are superimposed over price chart data to show the direction of the price movement and if the price is in a "overbought" or "oversold" state.

To improve results, traders have created numerous technical indicators and are constantly creating new versions. In order to determine how well new indicators would have predicted future occurrences, they are frequently back tested using historical price and volume data. A fake sign in the technical analysis suggests future value developments, which presents an inaccurate picture of the actual financial situation. A number of factors, such as timing slacks, inconsistent information sources, smoothing techniques, or even the computation used to generate the pointer, might result in false signals. By examining price movements and chart patterns in search of potential trading opportunities, technical analysis attempts to capture the psychology and sentiment of the market. Since indicators are not infallible, traders should exercise caution when selecting traders only on the basis of them.

II. EXISTING SYSTEM

Under Individual Grant AP086801, the Korea Institute for Advanced Study (KIAS) provided assistance for Eunho Koo's study. Grant NRF - 2017R1E1A1A03070886 from the National Research Foundation of Korea, issued by the Korea Government, provided funding for Geonwoo Kim's research. Precisely estimating volatility is among the most crucial responsibilities in making financial decisions.

Recently, hybrid models that combine GARCH-type models with artificial neural networks have been constructed, and the models' performance benefits have been proven to be exceptional.

III. PROPOSED SYSTEM

One of the most popular methods of managing finances is stock investing, and many individuals utilise technical indicators to determine when to purchase and sell stocks. This study suggests a unique way to make the most out of the widely used technical indicator, the Relative Strength Index (RSI). To identify the optimal approach and maximise profit, we first broaden all the possibilities in RSI by eliminating the constraint of the classic RSI's default parameters.

IV. ALGORITHM USED

The source of the dataset was Yahoo Finance. We regarded the data from Oracle Corporation (ORCL) as moderately volatile and the data from Intuit Inc. (INTU), which was likewise gathered from Yahoo Finance, as highly fluctuating.

We gathered data for 20 years (from June 30, 2000, to July 21, 2020) for each of these datasets, and there are 5044 cases total in each dataset. Traded volume, date, adjusted close price, high price, low price, close price, and adjusted close price are the seven properties that are present in every dataset.

The datasets that were gathered contained very few null values. It can effectively handle the null values because they have the potential to upset the real pattern of the price movement. Using the mean of the price for the preceding 30 days is a commonly used technique to replace the null value. This is how we resolved the problem. Additionally, we gathered information in one-day time interval format. Thus, pre-processing was not required for our one-day proposed Model. Nevertheless, we had to transform one-day time interval data into three-day and five-day time-interval datasets for the two-day and five-day models.

We modified things in the following ways for this reason.

- 1) The first day of the three and five-day periods.
- 2) Open price: The starting price for the first day of the three and five-day periods.
- 3) Highest price: The most expensive price during the course of three and five days.
- 4) Cheapest pricing: The lowest pricing for the full three and five-day periods.
- 5) Close Price: The final day's closing price for the three and five-day periods.
- 6) Traded Volume: The total amount of money exchanged over the course of three days and days.

Yahoofinancer.com is the source of the price data sets for the stock tickers because it is the API that is being utilised. Preprocessing involves resizing the photos in accordance with system specifications and filtering the price data in accordance with those requirements before pushing the data into the array and processing it using an LSTM model.

The data is divided into 80 and 20 percent to satisfy the model's needs. Twenty percent of the data is used for testing, while the remaining eighty percent is used for training. The construction of the trading model, which is done using the RSI algorithm, is the next stage. Testing is done to make sure the project is viable. Following completion of all of this work, the model is implemented.

V. MODULE DESCRIPTION

- 1) Step1: Gathering data

Yahoo Finance was the source of the dataset.

We regarded the data from Oracle Corporation (ORCL) as moderately volatile and the data from Intel Inc. (INTU), which was also gathered from Yahoo Finance, as highly fluctuating. We have 5044 instances in each of these datasets, which we gathered during a 20-year period (December 9, 2009, to December 31, 2021). The date, open price, low price, close price, adjusted close price, and traded volume are the seven attributes that are present in each dataset.

Date	High	Low	Open	Close	Volume	Adj Close
2009-12-31	7.619643	7.520000	7.611786	7.526071	352410800.0	6.444381
2010-01-04	7.660714	7.585000	7.622500	7.643214	493729600.0	6.544688
2010-01-05	7.699643	7.616071	7.664286	7.656429	601904800.0	6.556002
2010-01-06	7.686786	7.526786	7.656429	7.534643	552160000.0	6.451720
2010-01-07	7.571429	7.466071	7.562500	7.520714	477131200.0	6.439793

Date	High	Low	Open	Close	Volume	Adj Close
2021-12-27	180.419998	177.070007	177.089996	180.330002	74919600.0	180.100540
2021-12-28	181.330002	178.529999	180.160004	179.289993	79144300.0	179.061859
2021-12-29	180.630005	178.139999	179.330002	179.380005	62348900.0	179.151749
2021-12-30	180.570007	178.089996	179.470001	178.199997	59773000.0	177.973251
2021-12-31	179.229996	177.259995	178.089996	177.570007	64062300.0	177.344055

2) Step 2: Data processing

Using LSTM, we must first preprocess this data before adding the stock price. Use the fit transform function to change the values in our data. The data is scaled using a min-max scaler to enable us to bring all of the price values to a single scale. Next, we allocate the remaining 20% for testing and the remaining 80% for training to other variables.

Application of our LSTM model:

We develop our LSTM model in the following phase. The Sequential model that was imported from Keras and the necessary libraries were imported for this article. In our model, we employ two LSTM layers with dropout implemented in between for regularisation. The LSTM parameters have fifty units allocated to them. with a 10% dropout rate. The loss function for using the Adam optimizer to optimise the issue is mean squared error.

The statistic utilised in our LSTM Network in relation to time-series data is mean absolute error.

```

3) Step 3: Divide the Information

Following the pre-processing stage, the data is divided into two batches: the first contains eighty percent of the training data, and the second contains the remaining knowledge for testing. Each dataset includes the preferred stock price for each stock.

4) Step 4: Constructing the Model

The six-stage model construction process is the following step. Building the enhanced training programme. In order to save the model for the long-run prediction approach, the basic model using LSTM must first be added parameters, collected, trained, and saved.

5) Step 5: Examining the Model

There are steps in the model testing process to ensure the model can predict well. Predictions are made on the testing set as the initial step.

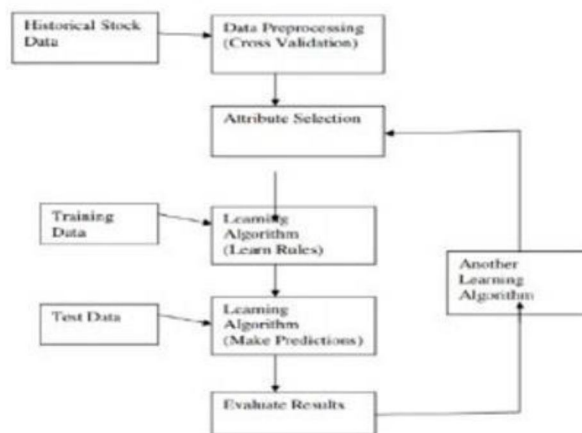

6) Step 6: Applying the Model

Firstly, we viewed the information by downloading the CSV file from Yahoo Finance. More than a decade's worth of data are included in these CSV files, more than enough for this tutorial. We are now importing the necessary libraries.

- import pandas as pd
- import yfinance as yf
- import pyplot as plt and matplotlib

After that, we'll read the CSV file that I downloaded from Yahoo Finance.

Additionally, you can obtain data by utilising the yfinance Python package, which is offered by Yahoo Finance.

7) Step: 7 Creating a New File

- Now we create a new file to make sure that can trade and not just view the assets chosen by the user.
- Now we move onto implementing the buy sell triggers.

8) Step: 8 Importing the Modules

```
import yfinance
```

```
import numpy
import ta
import pandas
```

9) Step 9: Obtaining the Information

- At this point, we obtain the data from Yahoo Finance and further provide the ticker name, initial data, data account, and interval.
- Additionally, we obtain the data frame pertaining to the price's high, low, close, and open. Additionally, we utilise the "ta" library to obtain the trend generated in the moving average convergence and divergence as well as the momentum formed in the relative strength index.

10) Step 10: Describe the process by which trigger signals are obtained

- First, we look for the intersection of the %k and %d lines.
- The %K line establishes a price range by comparing the lowest low and highest high points of a specific time frame. It then shows the most recent closing price as a range and as a percentage of this range. The %D line represents the %K moving average. On a scale from 1 to 100, these two lines are displayed, with key trigger levels at 20 and 80.
- We build a Boolean mask that enables value filtering in numpy arrays.

11) Step 11: Identifying the Buy and Sell Triggers

- Now that we have defined get triggers, we are using the data frame as the inputs, which gives the amount of lags—that is, the precise number of time steps you wish to travel back.
- Next, we set buy="True" as the default argument.
- Currently, we execute an if statement on the purchase and attach the mask to it.
- The mask will contain the values %K < 20 and %D < 20 for the if condition and the values %K > 80 and %D > 80 for the else condition.
- We now refer to the function as "get triggers" in order to obtain the buy triggers.

12) Step:12: Conditions for buying and selling (RSI, MACD, Stochastic, and Trigger)

- The buying trigger will be the first condition once we construct a new column. Afterwards, our %K line must be in the range of 20 to 80.
- It is also necessary for our %D to match.
- Then, our MACD should be greater than 0 and our RSI more than 50.
- Currently, the criteria for the sell triggers will be: the RSI must be less than 50; the %K line must be between 20 and 80; and the %D must match the %K conditions.
- MACD ought to be less than zero.

13) Step13: Purchasing and Disposing of Dates

- We now need to obtain the dates for purchasing and selling, therefore we're going to create two empty lists and fill them with loop logic.
- In order to check if our buying column contains a buy signal, we are using a for loop to loop the size of the data frame and restrict it by 1.
- We are currently adding dates to our purchases. Similarly, when it comes to selling.

14) Step 14: Steer clear of multiple or useless positions

- It's possible that we will receive purchase dates and not have any selling dates towards the conclusion of the data frame.
- In order to prevent such, we are setting up a variable that will deduct the length of the selling dates from the length of the buying dates.
