Abstract: *This research explores various dental casting materials & their significance in forensic science. Traditional materials, such as- Dental stone, Plaster of Paris, & Dental wax have long been utilized in forensic investigations. However, advancements in materials science have led to the development of newer, more versatile options, such as- Epoxy resins, Polyurethane, & Alginate substitutes. Each material offers distinct advantages & limitations concerning ease of use, accuracy, & durability. Dental stone, a widely used & employed material, provides excellent detail reproduction & stability but lacks flexibility. Plaster of Paris, though economical, may not yield precise replicas due to its brittle nature. Dental wax, appreciated for its malleability & is susceptible to form deformation & degradation over time. In contrast, modern alternatives like- Epoxy resins & Polyurethane boast superior strength & dimensional stability, making them ideal for long-term storage of dental impressions. Epoxy resins, in particular, offer high fidelity reproduction of dental structures & resistance to moisture, temperature fluctuations. Polyurethane, known for its flexibility & durability, enables the creation of resilient dental models suitable for extensive forensic analysis. Furthermore, Alginate substitutes have gained popularity for their ease of use & compatibility with 3D Printing technology. These materials also offer quick setting times & adequate detail capture, facilitating rapid production of dental models for forensic examination. While, Traditional materials continue to serve a purpose, the adoption of advanced casting materials has revolutionized forensic odontology by enhancing- efficiency, precision & archival integrity.*

I. INTRODUCTION

Dental Casting Materials play a crucial role in restorative dentistry, enabling the fabrication of accurate & durable prosthetic devices. Dental Casting materials play their importance in forensic investigations, particularly in identifying individuals through the dental records. Over the years, Significant advancements have been made in the development of these materials, driven by the pursuit of improved mechanical properties, biocompatibility & esthetic qualities. However, the impact of these advancements extends beyond the realm/field of dentistry, as dental casting materials have gained forensic significance in the identification of individuals in both legal & investigative contexts. This research paper aims to explore the largest developments in dental casting materials, with a particular emphasis on their forensic applications. It will drive into the properties & composition of modern casting alloys, highlighting their advantages over traditional materials. Additionally, the paper will examine the techniques employed mainly in Forensic Odontology, such as- Dental Profiling, Bite Mark Analysis, & how the advancements in casting materials have facilitated more accurate & reliable identifications. By bridging the gap between Dental Materials Science & Forensic Odontology, this paper seeks to underscore the interdisciplinary nature of scientific progress & its potential to impact various fields. The forensic significance of Dental Casting Materials not only aids in criminal investigations but also plays a vital role in disaster victim identification & historical anthropological studies, underscoring the far-reaching implications of this area of research.

II. HISTORICAL BACKGROUND

The use of dental evidence in forensic investigations dates back to ancient civilizations, where teeth were used for identification purposes. However, it wasn't until the late 19th century that the field of forensic odontology gained more recognition. In 1897, Dr. Oscar Amoedo, also known as, "The Father of Forensic Odontology" presented the first documented case of using dental records for identification. The early Dental Casting materials were primarily gold alloys, which were introduced in the 19th century. These alloys were valued for their durability & resistance to corrosion, but they lacked the esthetic qualities desired for restorations in visible areas of the mouth. In the 1930s, the development of dental Porcelain & Porcelain-fused-to-metal restorations marked a significant advancement in dental casting materials, allowing for more natural-looking restorations.

This improvement in esthetics also had implications for Forensic Odontology, as it enabled more accurate comparisons of dental records with the dental remains. The mid-20th century saw the introduction of base metal alloys, such as- Nickel-Chromium, & Cobalt-Chromium, which offered better mechanical properties & lower costs compared to precious metal alloys. These advancements paved the way for more affordable & durable dental restorations, expanding access to dental care & subsequently increasing the potential for dental evidence in forensic investigations. In recent decades, the development of Computer-aided design & manufacturing (CAD/CAM) technologies has revolutionized the production of dental restorations, enabling the use of new materials like- Zirconia & Lithium disilicate. These advanced materials offer superior strength, good biocompatibility, & esthetic qualities, further enhancing the accuracy of dental evidences in the Forensic Casework. As dental materials continue to evolve, their forensic significance is expected to grow, providing valuable tools for victim identification, age estimation, & crime scene analysis along with other applications.

III. TYPES OF DENTAL MATERIAL IN CASTING

A. Dental Stone

It's a type-III Gypsum product. It is a commonly used casting material in Forensic Odontology. It's made by making gypsum powder with Water to form a thick liquid that hardens into a solid when set. Dental stone is preferred for its ease of use, affordability, & ability to produce detailed casts of teeth & bite marks.

B. Dental Resin

Also known as, 'Dental Acrylic'; it's a polymer-based material that hardens when exposed to UV-light or, a chemical catalyst. Dental resin is often used when greater strength & durability of the cast are required, such as in cases involving bite mark analysis or, comparisons of dental prostheses. Composite resin is the most effective & widely used in dental resin used mainly for direct dental restorations & can be most relevantly used in bite mark analysis.

C. Precious Metal Alloys

Gold-based Alloys; These were among the earliest casting materials used in dentistry, valued for their biocompatibility, corrosion resistance & ductility. Gold-platinum & Gold-palladium are the two most common dental Gold-based alloys which are used all over the world & can be used as dental profiling. Palladium-based Alloys; Introduced as an alternative to gold alloys, these offer similar properties but at a lower cost; that's why, now a days many labs prefer this material for dental profiling.

D. Base Metal Alloys

Nickel-Chromium Alloys; These affordable & durable alloys became popular in the mid-20th century, offering high strength & resistance to tarnishing. This material is mainly used for comparisons for dental prosthesis. Cobalt-Chromium Alloys; These materials are known for their excellent mechanical properties, biocompatibility, & resistance to corrosion, these alloys are widely used for metal-ceramic restorations.

E. Titanium & Titanium Alloys

Commercially Pure Titanium; This biocompatible metal is used for dental implants & some restorations due to its strength & corrosion resistance. These type of casting materials are also used in analysis of bite marks. Titanium Alloys; These alloys offer improved mechanical properties compared to pure titanium, making them suitable for larger dental restorations. Ti-6Al-4V is one of the most widely used titanium alloys.

F. Ceramic Materials

Glass Ceramics; These materials combine the esthetics of Porcelain with improved strength & fracture resistance, making them suitable for Crown & Bridge preparation. Most widely used one is, Lithium Disilicate and mostly used for dental records correction & data report preparation. Polycrystalline Ceramics; Mainly known for their exceptional strength & fracture toughness, these materials are increasingly used for dental Crowns, Bridges & Implant Abutments. Zirconia is one of the most widely used polycrystalline ceramics mainly used to bite marks analysis.

G. Computer-Aided Design & Manufacturing (CAD/CAM) Technology

The introduction of CAD/CAM systems has revolutionized the fabrication of dental restorations. This technology allows for digital design & precise milling or, 3D printing of restorations from solid blocks of advanced materials like- Zirconia, Lithium disilicate or, even Metals. CAD/CAM restorations offer superior fit, accuracy, & efficiency compared to traditional casting methods. Improved esthetic outcomes in dental restorations.
