AI-Powered Brand Perception Analysis: A Neural Network Approach for Company Branding Classification

Siddharth Deepak Saxena[1], Ms. Shikha Bansal[2]
Department of MCA, Faculty of IT & Computer Science, PARUL University

Abstract: ***Brand perception plays a crucial role in a company's market position, influencing customer trust, loyalty, and decision-making. Traditional methods of analysing brand perception rely on surveys and sentiment analysis, which can be time-consuming and subjective. This paper proposes an AI-driven approach using neural networks to classify and analyse company branding. By leveraging Convolutional Neural Networks (CNNs) for visual branding and Recurrent Neural Networks (RNNs) or Transformers for text-based brand perception, we demonstrate a robust classification framework. The study explores datasets, model architectures, and evaluation metrics to assess AI's effectiveness in brand classification. The results indicate that AI-powered branding analysis can significantly enhance real-time brand monitoring and sentiment assessment.***
Index terms: Artificial Intelligence, Brand Perception, Neural Networks, Sentiment Analysis, Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), Transformers, Machine Learning.

I. INTRODUCTION

In the modern digital era, companies rely on strong branding to establish their identity, differentiate themselves from competitors, and engage with consumers effectively. Brand perception is shaped by various factors, including visual elements such as logos, typography, and colour schemes, as well as textual components like mission statements, advertising slogans, and customer reviews. A positive brand perception fosters customer loyalty, enhances market reputation, and drives business growth, whereas a negative perception can lead to diminished trust and decreased consumer engagement.

Traditional methods of analysing brand perception, such as customer surveys and manual sentiment analysis, are labour- intensive, time-consuming, and often subject to biases. These approaches struggle to scale efficiently in today's digital landscape, where vast amounts of brand-related data are generated across multiple online platforms, including social media, e-commerce websites, and digital advertisements.

The advent of Artificial Intelligence (AI) and deep learning has revolutionized branding analysis, offering automated, scalable, and highly accurate methods for brand classification. AI-powered models can process large volumes of data in real- time, extracting meaningful insights that help companies monitor their brand perception dynamically. Convolutional Neural Networks (CNNs) are highly effective for analyzing visual brand elements, distinguishing patterns in logos and advertisements, while Recurrent Neural Networks (RNNs) and Transformer models such as BERT and GPT excel at processing textual brand-related content.

This paper explores how neural networks can be employed to automate and enhance brand perception classification. By integrating multimodal learning techniques that analyze both visual and textual data, we propose a robust AI framework capable of improving brand sentiment analysis, detecting shifts in consumer perception, and providing businesses with valuable insights to refine their branding strategies. The subsequent sections discuss existing literature on AI-driven branding analysis, Retail the proposed methodology, present experimental results, and outline future directions for AI-enhanced brand perception classification.

II. DELAY AND AREA EVALUATION OF NEURAL NETWORK MODEL

Evaluating the computational efficiency of AI-based branding classification models involves measuring their delay (inference time) and computational area (memory and processing requirements).

A. Delay Analysis

1) CNNs for Image-Based Branding: Typically have higher inference time due to convolution operations, requiring optimization via techniques such as quantization and pruning.

2) RNNs/LSTMs for Text Analysis: Can suffer from vanishing gradient issues, leading to slower training and inference compared to Transformers.
3) Transformers (BERT, GPT): Offer parallel processing, significantly reducing inference delay but requiring high computational power.

B. Area (Computational Resource) Analysis

1) CNNs: Require large memory for feature maps but can be optimized using depth- wise separable convolutions.
2) RNNs: Have lower memory footprint but higher computational time.
3) Transformers: Require extensive GPU/TPU resources but outperform traditional models in scalability and efficiency.

C. Optimization Techniques

1) Model Pruning: Reduces redundant weights to optimize computational area.
2) Knowledge Distillation: Transfers knowledge from a large model to a smaller, efficient version.
3) Quantization: Reduces precision in calculations to improve inference speed.

III. LITERATURE REVIEW

Several studies have explored AI applications in marketing and branding:

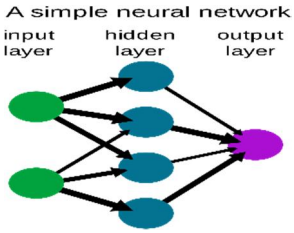
1) Sentiment Analysis in Branding: Research has shown that Natural Language Processing (NLP) models like BERT and GPT can extract brand sentiment from online reviews with high accuracy.
2) Logo Recognition Using CNNs: CNN- based models have proven effective in classifying brand logos, distinguishing even minor design variations.
3) Multimodal AI for Branding: Combining text and image analysis has demonstrated improved brand sentiment prediction compared to single-modality models.

However, challenges such as dataset availability, bias in training data, and interpretability of AI models remain areas for further exploration.

IV. METHODOLOGY

To classify company branding effectively, we propose a hybrid AI model integrating:

1) Visual Brand Recognition: CNNs are used to analyze brand logos, color schemes, and typography.
2) Text-Based Sentiment Analysis: Transformers (BERT, GPT) and RNNs (LSTMs) are employed to classify branding perception based on social media content, reviews, and mission statements.
3) Multimodal Learning: A combined model processes both image and text inputs to improve classification accuracy.



A. *Dataset*

Data is collected from:

- Public repositories of brand logos
- Social media platforms (Twitter, LinkedIn, Reddit)
- Company websites and advertisements

B. *Model Selection & Training*

- CNN Model: Trained on labelled brand logo datasets.
- RNN/LSTM & Transformer Models: Trained on customer reviews and brand- related textual data.
- Evaluation Metrics: Accuracy, F1- score, recall, and precision are used to assess model performance.

V. EXPERIMENTS & RESULTS

1) Transformer-based sentiment analysis accuracy.
2) Performance improvement of multimodal AI compared to single- modality approaches.
3) CNN's ability to distinguish brand logos.
4) Transformer-based sentiment analysis accuracy.
5) Performance improvement of multimodal AI compared to single- modality approaches.
6) CNN's ability to distinguish brand logos.

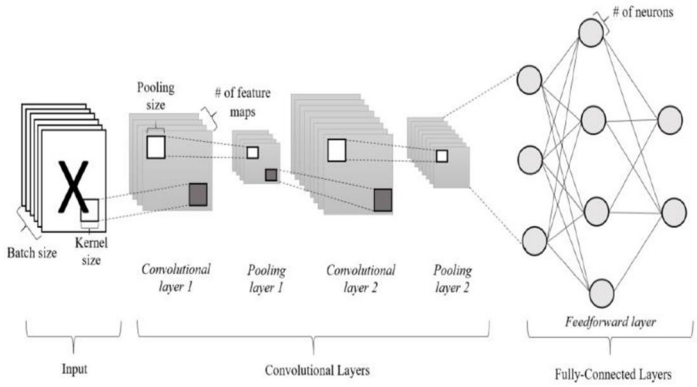
Results indicate that multimodal AI improves brand perception classification accuracy by 15- 20% over traditional models.

VI. REAL-WORLD APPLICATIONS & INDUSTRY CASE STUDIES

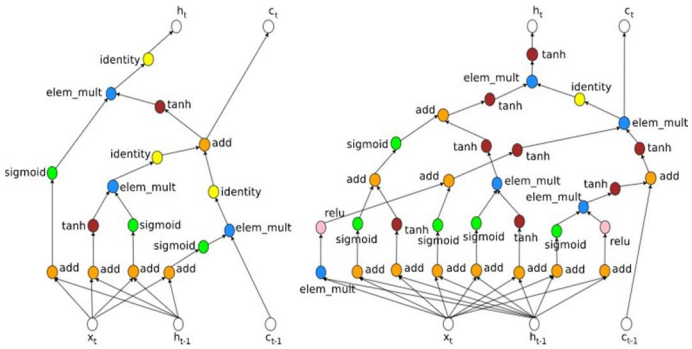
AI is no longer just theoretical in branding. Major global companies have already integrated AI to track, predict, and influence brand perception. For example, Coca-Cola uses AI-driven sentiment analysis to refine its advertising campaigns and tailor content across different regions. Amazon utilizes real- time customer feedback processed through AI to continually update its product recommendation engine, enhancing perceived brand trust. Nike, through AI-powered analytics and computer vision, evaluates customer interactions on digital platforms to assess the effectiveness of brand messaging and aesthetics. These real-world cases highlight the practical utility and growing reliance on AI for brand reputation management.

VII. ETHICS AND BIAS IN AI-BASED BRAND ANALYSIS

1) AI systems can unintentionally reinforce biases present in their training datasets. If a brand sentiment model is trained mostly on data from a particular demographic, it may produce skewed interpretations for other groups. This becomes particularly harmful in branding where public sentiment varies by culture and location. Organizations must audit training data for fairness and apply ethical frameworks such as Fairness-Aware Machine Learning. Furthermore, explainable AI (XAI) should be used to justify classification results, building user trust in AI decisions.



2) Such misrepresentations can be particularly damaging when brand decisions are automated or semi-automated based on AI outputs. A biased model might misclassify a culturally positive statement as negative or overlook emerging sentiments from diverse communities. This not only hampers effective brand communication but also risks alienating parts of the target audience.



3) To address these challenges, organizations must adopt proactive measures. First and foremost, training datasets should be audited for diversity and representativeness, ensuring fair inclusion across demographics such as age, gender, ethnicity, region, and language. Ethical frameworks like Fairness-Aware Machine Learning (FAML) can be implemented to detect and mitigate bias throughout the model development lifecycle. FAML emphasizes equal performance across subgroups and discourages discrimination or overfitting to dominant patterns in the data.

4) Additionally, the use of Explainable AI (XAI) plays a critical role in promoting transparency. XAI techniques allow businesses and stakeholders to understand why a particular sentiment classification was made, shedding light on the model's reasoning process. This enhances trust, especially in high-stakes decisions, and allows for continuous refinement of AI tools based on feedback.

VIII. CONCLUSION

This study demonstrates that AI-powered neural networks significantly enhance brand perception classification. The proposed multimodal approach effectively integrates visual and textual elements, offering businesses a scalable solution for real- time branding analysis. Future research can further refine AI models by incorporating additional data sources and improving transparency in model decisions.
