An Early Clock Based Multi Tap Flexible H-Tree for High Performance CPU Design for Achieving Best Cross Corner Scaling

Mukul Anand¹, Nikunj Tripathi²

MDG-GPM, STMicroelectronics, Greater Noida, India

Abstract: The High-Performance Designs need a robust Clock Tree which achieves a low skew, insertion delay and minimum power. A Conventional CTS does not provide an optimal solution to these. The Proposed methodology enables an early clock Based flow for a Multi-Tap Flexible H Tree Clock Tree Generation. The Early Clock Flow will build a preliminary Clock Tree at placement helping in achieving a clock gate enable timing estimation and better placement. The Multi Tap Flexible H Tree helped in best cross corner scaling as well as electrically and geometrically symmetry.

Keywords: Clock Jitter, Multi-Source CTS (Clock Tree Synthesis)

I. INTRODUCTION

A Customized Clock Tree Synthesis (CTS) is typically designed for better cross corner scaling. It has a combination of large drivers and low RC delay routing layers (Top Layers) to reduce clock latency. Widely used such structures are the H-tree and an H-tree driving a clock mesh. The *Flexible H-Tree* form of CTS provides the *electrically symmetric* buffering and balanced wire length benefits of an H-tree, but relaxes the requirement to be *geometrically symmetric*, enabling auto-mated synthesis. This is applicable even in floorplans with placement restrictions. *Multi-Tap Clock Tree Synthesis*, also known as Multi-Source Clock Tree Synthesis, is fully integrated with the Flexible H-tree feature and extends regular clock synthesis to provide local buffering and balancing between the structured top of tree and the clock sinks.

In the PnR implementation flow, the clock tree cells are not inserted during placement stage. Therefore, PnR tool cannot consider routing congestion caused by the addition of clock tree cells and even the clock gating timing paths are inaccurate. Early Clock Flow (ECF) is inserting a preliminary clock tree during placement optimization stage, using a fast clock tree clustering by annotating the clock latencies for timing optimization. A clock tree during placement stage normally results in a better standard cell placement and congestion estimation. ECF includes clock gating timing path estimation as well. This can result in better timing because pre-CTS optimization has more timing impact than post-CTS. ECF uses Concurrent clock and Data optimization (CCOPT) with useful skew technologies, doing late as well as early skewing. This Paper has taken a CPU Design which has 5 million Gates and 1.2GHz Frequency. The size of Block was 1000um X 1000um. Cadence Innovus Flexible H Tree with Multi Tap feature was employed. This feature has less CTS run time but better electrically symmetrical buffering, balanced wirelength which helps in achieving a low skew and better geometrical symmetric CTS.

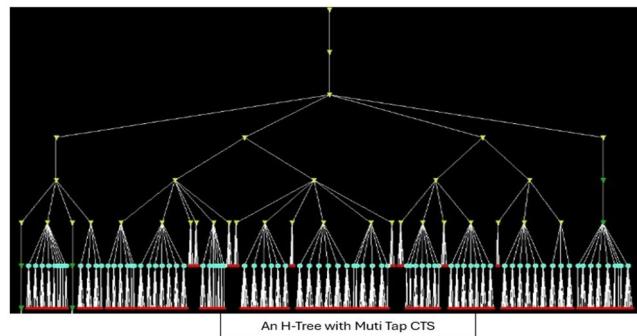

The Results show that Multi Tap Flexible H-Tree used in Pre-CTS and CTS stage gives a better result for High Frequency design like CPU's which are working at 1.2GHz and beyond.

II. CLOCK TREE SYNTHESIS STRATEGY

A. Overview of a Flexible H Tree

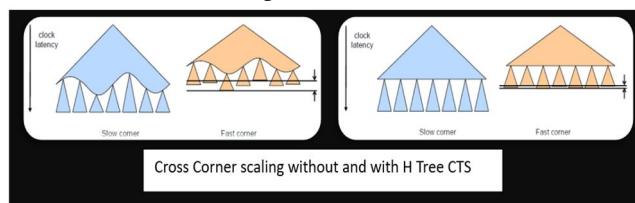

An H-tree alone is not the replacement for the Conventional Clock Tree. Conventional CTS is required to complete the buffering and balancing required between the sinks of the H-tree and the clock sinks. Fig 2 below shows the logical structure of an H Tree. The root pin is a cell instance or an external input port. It is a starting point for the signal to be distributed across the H-tree. The output pins of the H-tree sinks (in red), serve as multiple sources for multi-tap CTS, which will synthesize the sub-trees underneath each tap.

A regularly spaced grid of sinks leads to a more efficient H-tree due to the need for electrical symmetry. Clock Tree synthesis algorithm exploits the regularity of a sink grid when determining the H-tree topology.

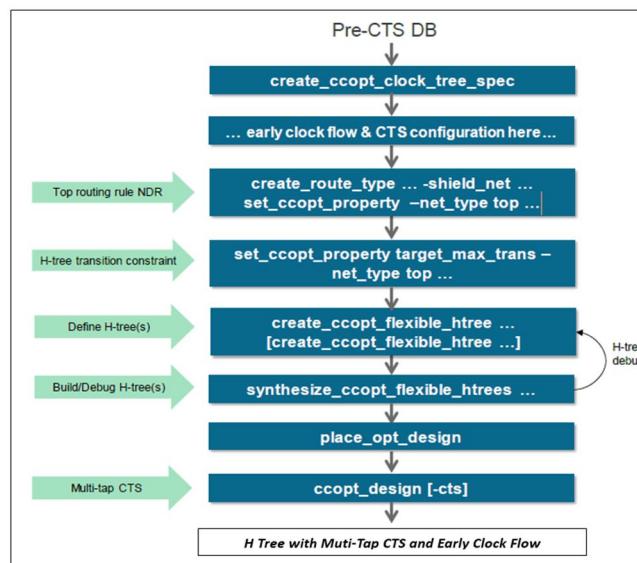

Cross Corner scaling: This picture below depicts a Conventional CTS which has been balanced primarily considering a slow corner. This Tree has been split into upper and lower sections. Conventional CTS achieves a balanced tree via a mix of cell insertion, sizing and wire length adjustment that may take place in both upper and lower sections of the tree. When timed in a fast corner, the delays of different cell sizes or cell types may scale differently to one another and differently to the RC delay of the connecting wires, leading to skew. Depending on the locality of timing paths and the purpose of the delay corners, this can lead to harder setup/hold timing closure.

In Case of the H-Tree CTS, top of tree is electrically symmetric and maintains a perfect skew over all delay corners. The skew at the sinks is correspondingly reduced in the fast corner when compared to Conventional CTS.

B. Early Clock Flow Based Placement

The ECF enables the tool to measure and optimize for the impact of multi-tap CTS clock gate cloning earlier in the flow when more powerful optimization transforms such as pre-CTS skewing, critical path placement changes, and multi-bit flop optimization are available.

After building the initial clock tree, several iterations between incremental placement, timing optimization, useful skewing, congestion repair, power optimization, will follow. Inside optimization, there are several useful skew passes.

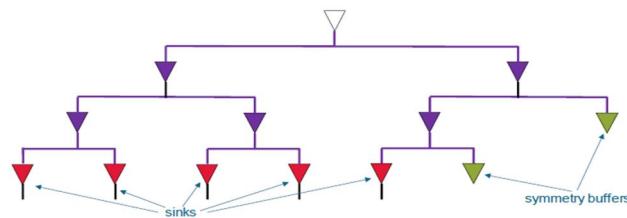

A basic sample script for the ECF can be referred as below:

```

set_multi_cpu_usage -local_cpu 8
read_db cpu_design.enc
set_db design_early_clock_flow true
set_clock_buffer_cells {HDBLV16_BUFSKR_16 HDBLV16_BUFSM_12 HDBLV16_BUFSKF_16 HDBLV16_BUFSINV_10 HDBLV16_INV_S_10 HDBLV16_INV_S_12 HDBLV16_INV_S_14}
set_clock_inverter_cells {HDBLV16_INV_S_10 HDBLV16_INV_S_12 HDBLV16_INV_S_14}
set_icgCells {HDBLV16_CKGTPLT_VTOP1_16 HDBLV16_CKGTPLT_V7_12 HDBLV16_CKGTPLT_V5_16}
create_ccopt_clock_tree_spec -file ccopt.spec
source ccopt.spec
set_db cts_buffer_cells $clock_buffer_cells
set_db cts_inverter_cells $clock_inverter_cells
set_db cts_clock_gating_cells $icgCells
synthesize_ccopt_flexible_htrees
set_ccopt_property extract_balance_multi_source_clocks true
place_opt_design
ccopt_design
  
```

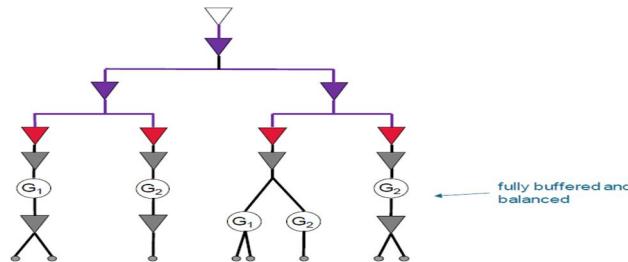

C. Multi Tap H-Tree CTS advantage Normal H-Tree

Flexible H-tree synthesis will by default insert symmetry buffers (which might be inverters) to ensure electrical symmetry. The example below shows a Flexible H Tree that contains two symmetry buffers where three sinks are missing from a tree, which otherwise will be expected to have eight 11. The symmetry buffers serve the purpose of ensuring a balanced pin load and routing structure (that is, electrical symmetry).

Multi-tap CTS is quite simply regular CTS/CC-Opt. The multi-tap functionality is enabled by the existence of one or more clock tree source groups.

CTS will perform multi-tap assignment, cloning if required, and will place the clones as part of regular CTS placement and buffering. Balancing will take place per the skew group definitions. Typically, a single skew group will balance all sinks under the H-tree together.

D. Image debug output details

To aid debugging, flexible H-tree synthesis can output PNG format image files that represent the synthesis algorithm view of the floorplan, sink grid, and H-tree.

Color/Shape	Purpose
white grid	The synthesis grid
red	Grid points that are blocked for trunk cell placement
orange	Grid points that are blocked for final cell placement
red-orange	Grid points that are blocked for both trunk and final cell placement
yellow circle	Root pin
yellow cross	Target location for an H-tree sink to be inserted
yellow rectangle	Sink area, as per -sink_grid sink_area or user specified area with -sinks
brown rectangle	Sink grid bounding box if -sink_grid_box is specified
green/blue	Intended edges of the synthesized H-tree (<htree_name>.tree.png only)
yellow dots	H-tree drivers (<htree_name>.tree.png only)

III. EXPERIMENTAL SETUP AND RESULTS

H-tree synthesis operates on an internal synthesis grid and all features are aligned to that grid.

Image 1: - This shows the Proposed H Tree Layout for the current Design and the location of the Drivers.

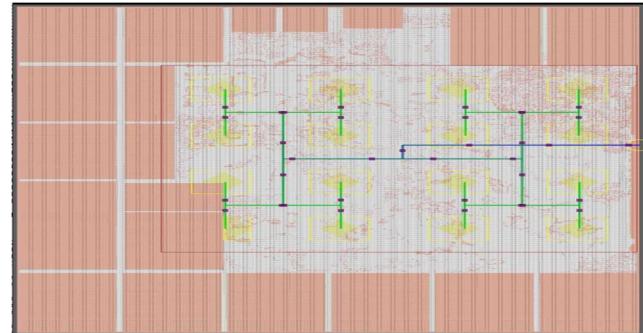

Image 2: - This shows the Floorplan and the Sink Grid

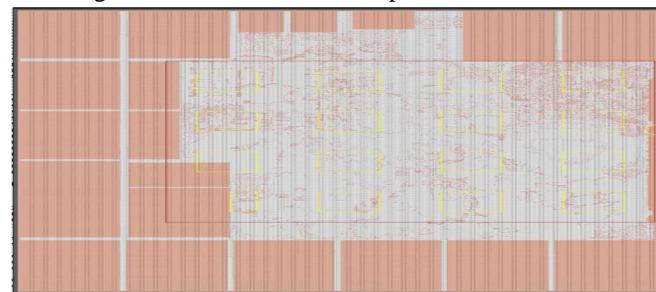

Image 3: - Flexible H-Tree with Multi Tap for one Clock

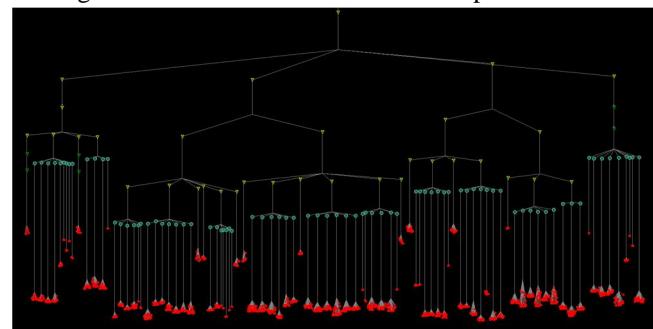

Image 4: - Design view with Proposed CTS

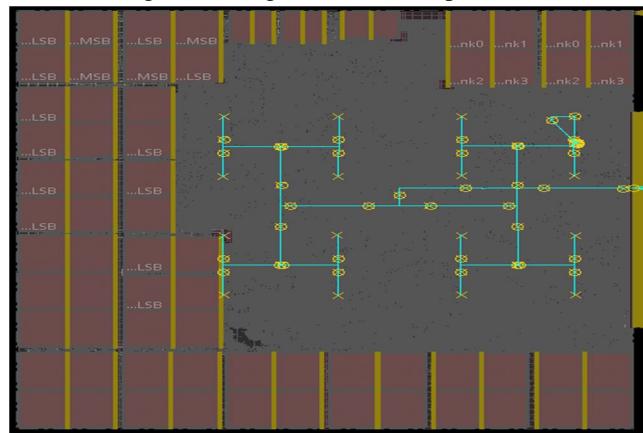

Table 1: - Timing Numbers for the Different Placement

Experiment	Placement (WNS/TNS/FEP)	CTS Opt (WNS/TNS/FEP)
No ECF	-0.282/1301.121/12849	-0.291/1758/21475
ECF with Conventional CTS	-0.170/-892.432/8817	-0.220/-965.79/9287
ECF with Multi Tap Flexible H tree	-0.149/-465.791/5347	-0.182/-519.79/6321

Table 2: - Clock Summary Comparison

Clocks (NIC_AHB_CLK _clk)	Clock Gates	Buffer	Inverter	Max_length (um)	Standard Cell Area (um^2)
Conventional CTS	3419	0	4150	245.38	4770.62
Flexible H Tree Multi Tap CTS	4772	0	1593	123.33	5017.02

	Latency (ns)	Skew (ns)	CTS Routing Layer	CTS Cells	Max/Min Clock Level
Conventional CTS	1.26	0.042	M3-M6	HDBLV16_INV_S_12 HDBLV16_INV_S_10 HDBLV16_INV_S_9 HDBLV16_INV_S_8	32/43
MultiTap CTS	0.849	0.036	M5-M7	HDBLV16_INV_S_16 HDBLV16_INV_S_14 HDBLV16_INV_S_12 HDBLV16_INV_S_10	14/24

Table 3: - Power Comparison

Power Comparison (mW)	Internal	Leakage	Switching	Total	Voltage (V)
Conventional CTS	813.6	189.2	555.7	1559	0.99
MultiTap CTS	752.1	172	615	1539	0.99

IV. CONCLUSION

Balanced CTS optimization is really a great challenge. Based on unique insight into Clock skew and Latency , this novel methodology is proposed to optimize the CTS , which can achieve better clock latency and clock power compared with the results from Conventional Method of CTS build. This Proposed CTS Methodology can also improve TNS of setup as well hold timing, for the impact of OCV is reduced from the cross-corner scaling. This approach is useful for a better leakage power reduction. Further enhancements can be made by implementing this strategy on designs with more congestion and multiple power domains.
