Automated Engine Design using Machine Learning

Paras Raorane¹, Bhagyesh Rathod², Shubham Raut³, Sahil Sankpal⁴, Nilesh Shinde⁵

Datta Meghe College of Engineering

Abstract: Machine Learning has been widely used in solving complex problems across various fields for the past decade, and computers have become more powerful than ever before. Mechanical engineers have a responsibility to use these groundbreaking discoveries to improve existing instruments and methodologies for better efficiency in production. Technologies like Machine Learning, Deep Learning, and Computer Vision can automate complex design procedures and can be integrated with existing technologies to create the building blocks for the 5th industrial revolution. Computerized programs can be helpful in situations where resources like time and skilled labor are scarce. The project aims to use Machine Learning and other Python-based frameworks to develop an interactive interface for designing complex models, specifically a combustion engine.

I. INTRODUCTION

“Automated Engine Design using Machine Learning” is our attempt to utilize groundbreaking discoveries in computer technology to make designing complex 3-dimensional objects easier and less time consuming. The core idea is to develop an advanced python script to design any Engine as per the load requirements with or without any direct specification of parameters. The idea also includes building a voice assistance technology interface using Machine Learning models for voice recognition and Machine-human interaction. In short, it’s an end-to-end program which automates the process of design of an engine. The core task is to make a voice recognition program which takes a voice input (which may or may not explicitly specify any dimensions of design related to the engine) and return a designed CAD model of the same in “.stl”, “.step” or “.amf” format as per the choice or requirement. The project can be divided into two separate blocks according to the function: Front end and Back end. Front end: ML algorithm that predicts design specifications analyzing the voice input Back end: Algorithm that produces the 3D CAD model according to the specifications received from the Front end and returns the produced file in the required format of choice

II. OBJECTIVES

- 1) To solve complex design tasks & perform complex design procedures with the help of a computer
- 2) To develop a virtual assistive interface technology for Machine-human interaction
- 3) Use voice recognition for designing 3D objects
- 4) Develop a program that uses voice recognition to capture the requirements for a single/multiple cylinder petrol/diesel engine, analyzes the input, predicts the dimensions of the engine, & returns a 3D CAD model of the same in the required format of choice

III. METHODOLOGY OF PROJECT

The entire program can be divided into two parts: Front end: ML algorithm that predicts design specifications analyzing the voice input Back end: Algorithm that produces the 3D CAD model according to the specifications received from the Front end and returns the produced file in the required format of choice Following is a basic overview of the structure of the program:

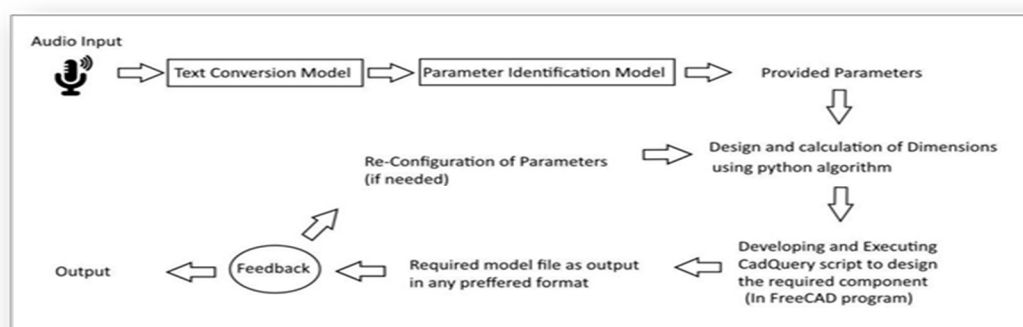

Figure 4.1 Basic overall architecture of the project

The upper flowchart explains the project's process for "Automated Engine Design using Machine Learning" with audio input as the main function. Users can manually enter values or use voice input, facilitated by the Vosk open-source speech recognition toolkit. Parameters are identified using pyttsx3, a Python library for text-to-speech conversion and calculated using pre-trained engine parameter code. If the design fails, users can provide new inputs. The parameters identification model identifies relevant parameters and executes the required procedures, with output customizable using pyttsx3's support for various voices, languages, and adjustable parameters such as volume, pitch, and speed.

The flowchart Figure 4.2 outlines the path from audio input to engine model design. The audio command is received through voice recognition technology, and then converted into text format using a speech-to-text model. The user inputs appropriate values for engine design parameters, with the interface suggesting the most efficient values. The engine design process begins, using the "Machine Design Data Book" for reference values. Theoretical engine design is achieved, and the interface displays it with reference page numbers for the user's understanding. The design can be saved as a PDF, and a 3D model is created using CAD Query Script. The user can then save the CAD model in the ".step" format to complete the process.

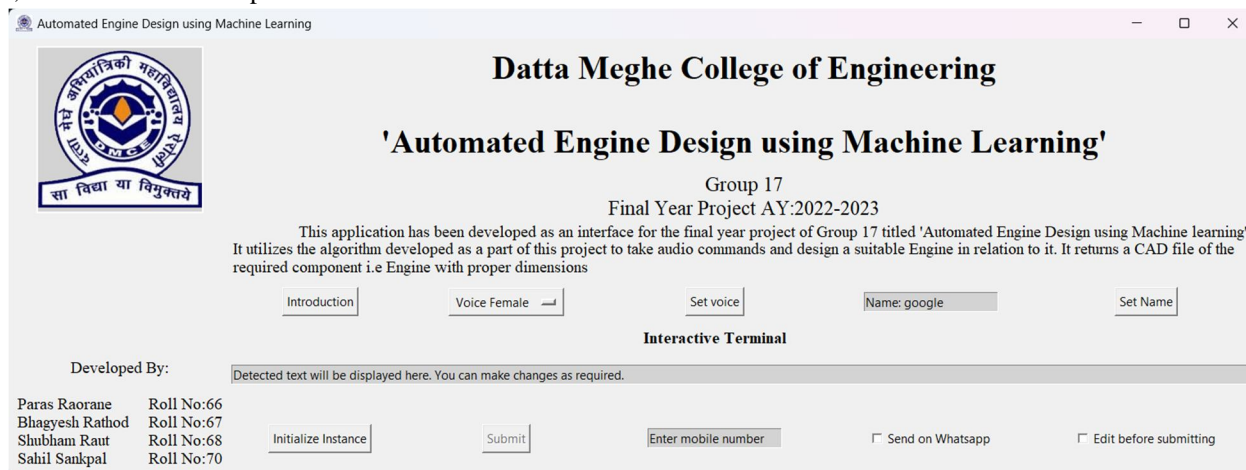

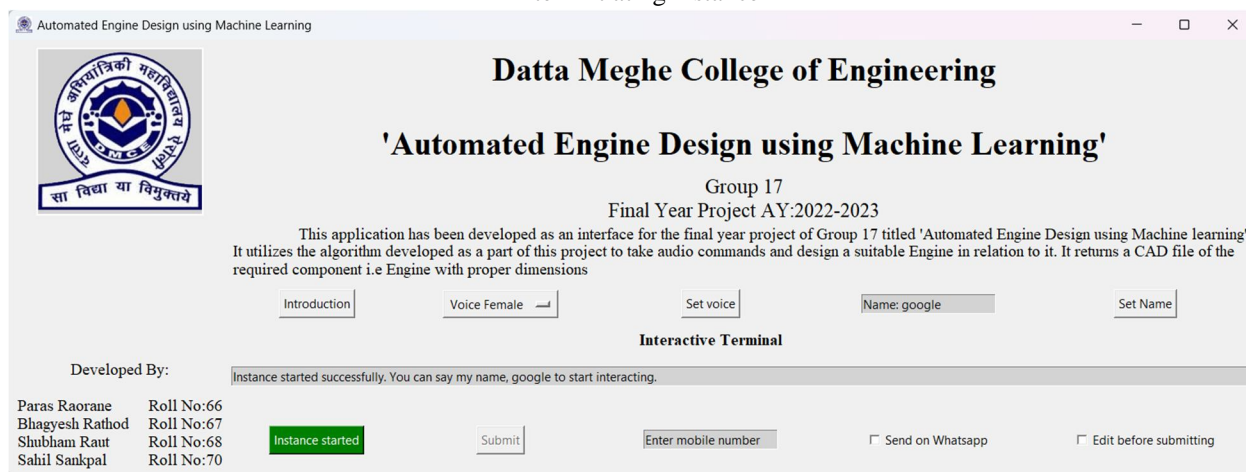

Figure 4.2 Detailed Architecture and Flow of Information

IV. DESIGN AND EXPERIMENTAL SETUP

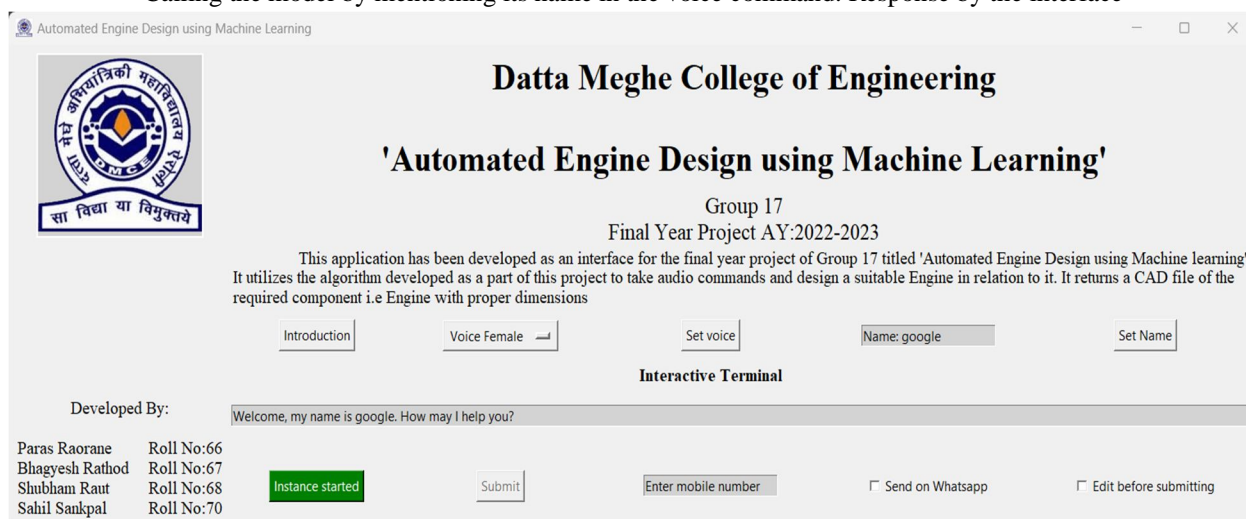

The following is the initial setup for the interface of the project. It consists of labels, description, convenience buttons, interactive terminal, and instance start/stop button.

After initiating instance

Calling the model by mentioning its name in the voice command. Response by the interface

Asking to stop the instance

'Automated Engine Design using Machine Learning'

Group 17
Final Year Project AY:2022-2023

This application has been developed as an interface for the final year project of Group 17 titled 'Automated Engine Design using Machine learning'. It utilizes the algorithm developed as a part of this project to take audio commands and design a suitable Engine in relation to it. It returns a CAD file of the required component i.e Engine with proper dimensions

VI. CONCLUSION & FUTURE SCOPE

The project demonstrates the capability of Python to automate design procedures, making the overall process more efficient and effective. The use of Python in automating design tasks has several benefits, including increased accuracy, faster processing times, and reduced human error. The project showcases the successful usage of Python in automating design procedures and tasks, highlighting the benefits of using Python in the design process. Virtual assistive interface technology represents a major step forward in the field of automation. It bridges the gap between humans and machines, making it easier for designers and engineers to interact with complex systems and machines. The potential applications of this technology extend far beyond engineering, including healthcare and transportation industries, improving safety and efficiency. In conclusion, computer-aided design tools are crucial for solving complex design tasks and procedures, and the development of virtual assistive interface technology has the potential to improve efficiency, reduce errors, and enhance safety across a wide range of industries.

VII. FUTURE SCOPE

The project presented highlights the potential of Python in automating design tasks and procedures, offering several benefits such as increased accuracy, faster processing times, and reduced human error. There are still several avenues for future research and development in this area. One future scope is the exploration of different machine learning algorithms that can be applied to automate design procedures. Python's machine learning libraries, such as Scikit-learn and TensorFlow, can be leveraged to create models that can learn from previous design data and generate design solutions based on specific requirements. Another area of future research is the integration of Python with other design software and tools. By seamlessly integrating Python scripts with other design software, engineers and designers can streamline their workflow and automate repetitive tasks. Furthermore, the development of virtual assistive interface technology presents a significant opportunity for future research and development. By enhancing the interaction between humans and machines, this technology can enable engineers and designers to collaborate more effectively with machines, potentially improving safety and efficiency across various industries. In conclusion, the application of Python in automating design tasks and procedures has several benefits, and there are several opportunities for future research and development in this area. Additionally, the development of virtual assistive interface technology has the potential to revolutionize how engineers and designers interact with complex systems, and improve safety and efficiency across various industries.
