Automating Enterprise IT Support: Design and Evaluation of an Autonomous AI Agent

Waleed K M[1], Dr. D. Jayasutha[2]
Department ofComputer Science and Engineering, Kathir College of Engineering

Abstract: ***In the rapidly evolving digital enterprise landscape, maintaining efficient and responsive IT support is critical for business continuity and user satisfaction. However, traditional support models that rely heavily on human agents frequently suffer from high operational costs, limited scalability, and slow resolution times for routine issues. To overcome these challenges, this paper presents the design, implementation, and evaluation of an autonomous, AI-powered IT Support Agent built to automate and enhance technical support services. By leveraging advanced natural language processing (NLP), machine learning, and deep integration with an enterprise knowledge base, the proposed system can intelligently interpret user queries, diagnose common technical problems, and provide real-time solutions without human intervention.***

The developed agent autonomously handles repetitive Tier-1 tasks such as password resets, software troubleshooting, network diagnostics, and automatic ticket generation. Crucially, the architecture includes an escalation module that seamlessly transfers highly complex issues to human technicians while preserving the complete context of the user's interaction. Implementation results demonstrate that the system continuously learns from user interactions to improve its accuracy over time. By deploying this AI-driven support ecosystem, organizations can significantly reduce response times, lower operational costs, and offer continuous 24/7 support. Ultimately, this solution vastly improves the overall user experience and organizational productivity while allowing human IT staff to dedicate their expertise to more complex, strategic initiatives.

Keywords: Artificial Intelligence, IT Support Automation, Natural Language Processing, Autonomous Agents, IT Service Management, Large Language Models

I. INTRODUCTION

The modern enterprise is increasingly reliant on complex and expansive Information Technology (IT) infrastructure, which has led to a corresponding surge in the demand for responsive and efficient IT support. Traditional IT service models heavily rely on human agents for every inquiry. These conventional systems face significant challenges, including high operational costs, slow resolution times for routine issues, and difficulty in providing 24/7 support.

Consequently, current IT support systems are frequently overwhelmed by a high volume of Tier-1 requests, such as password resets, account lockouts, and software installation requests. These tasks are highly repetitive, time-consuming, and require minimal human reasoning to resolve. This inefficiency results in longer wait times for users, reduced employee productivity, and increased user frustration, underscoring the necessity for a more scalable and intelligent solution. Furthermore, this continuous strain on resources prevents human IT staff from focusing their expertise on critical, high-impact strategic projects and escalated technical problems.

To address these pressing challenges, this paper presents the design and implementation of an autonomous Artificial Intelligence (AI) Agent capable of handling a significant portion of routine IT support tasks. The primary objective of this project is to deploy an intelligent, AI-based system capable of efficiently managing these routine operations. The proposed solution aims to significantly reduce response times, lower operational costs, and enhance user satisfaction by automating repetitive Tier-1 issues. By successfully managing software requests and password resets, the system enables human IT staff to focus on complex, high-value technical and strategic functions.

The scope of this implementation is centered around the development of an AI Agent that utilizes a Large Language Model (LLM) as its reasoning engine, paired with a custom knowledge base containing internal documentation and FAQs. To achieve true autonomy, the system features robust tool integration, equipping the agent with the ability to interact with common IT systems, such as Active Directory for password resets and ticketing systems for status checks. While the primary focus is on the autonomous resolution of predefined, common Tier-1 and Tier-2 IT issues, the system is designed to recognize its own limitations. It includes a mechanism for seamless human hand-off, allowing the AI Agent to intelligently escalate complex or critical issues to a human technician while providing the full context of the user's conversation.

II. LITERATURE SURVEY

The integration of Artificial Intelligence (AI) and Large Language Models (LLMs) into IT service management and technical customer support has seen rapid development, transforming traditional support paradigms into autonomous, self-healing ecosystems. This survey synthesizes recent advancements across AI agent architectures, efficiency impacts, knowledge management, and proactive system operations.

A. Evolution and Architecture of AI Agents

Krishnan explores the rapid evolution of AI agents from narrowly focused, task-specific systems to autonomous entities capable of perception, reasoning, and adaptive decision-making [1]. Powered by advancements in LLMs, modern AI agents integrate memory, tool-use modules, and planning to execute complex, goal-directed behaviors in enterprise automation and technical support [1].

To systematically evaluate these technological leaps, Ferrag et al. provided a comprehensive review of evaluation benchmarks and autonomous AI frameworks introduced between 2023 and 2025 [2]. They highlighted the integration of LLMs with modular toolkits and surveyed crucial agent-to-agent collaboration protocols, such as the Model Context Protocol (MCP) and Agent Communication Protocol (ACP), which enable multi-step reasoning [2].

For highly complex, dynamic systems, single agents are often insufficient. Duan and Wang explored multi-agent applications by integrating LangGraph and CrewAI [7]. Their research demonstrated how LangGraph's architecture improves precise control and information transmission, while CrewAI enhances team collaboration and system performance through intelligent task allocation [7].

Impact on Operational Efficiency and Customer Service

Applying these autonomous agents directly to customer service, Uzoka and Cadet found that AI-powered chatbots effectively reduce operational costs and response times while significantly improving customer satisfaction [3]. Their analysis revealed that these chatbots can successfully handle up to 70% of routine customer inquiries, directly allowing human agents to focus their expertise on more complex issues [3].

Supporting this empirical data, Wulf and Meierhofer investigated the feasibility of automating cognitive tasks in technical support using real-world incident data [6]. They discovered that while lower-level cognitive tasks—such as translation, content generation, and summarization—are easily automated using models like GPT-4, higher-level reasoning necessitates advanced technological approaches [6].

B. Knowledge Management and Retrieval-Augmented Generation (RAG)

To achieve the higher-level reasoning required for complex IT support, advanced knowledge retrieval is critical [6]. Noruzi identifies Enterprise AI and Retrieval-Augmented Generation (RAG) as the next generation of knowledge management [8]. RAG systems overcome the limitations of static databases by first retrieving relevant documents from large knowledge bases and then using that data to generate coherent, contextually accurate, and real-time responses [8].

Furthermore, Konda introduced a scalable smart tagging framework designed for enterprise environments [4]. By utilizing structured metadata and AI, this framework automates knowledge classification and enhances chatbot-driven self-service and multilingual content delivery [4].

C. Proactive IT Operations and ITSM Integration

Shifting the paradigm from reactive troubleshooting to proactive support, Venkatram highlighted the severe limitations of legacy IT monitoring systems, which rely on manual data correlation and static, hard-coded thresholds, ultimately leading to alert fatigue [5]. Instead, AI models are now heavily leveraged for proactive problem detection and root cause analysis to prevent prolonged incident resolution times and safeguard business continuity [5].

Integrating these advanced AI capabilities into the enterprise requires foundational IT service management frameworks [9]. Standardized practices, such as the ITIL 4 framework, remain essential for ensuring that AI-driven automations align with overall business service delivery [10]. The backbone of these human-to-machine interactions relies on robust Natural Language Processing (NLP) to parse user intent accurately within service automation chatbots [11]. This integration paves the way for Applied Artificial Intelligence in IT Operations (AIOps), creating resilient IT infrastructures [12]. Ultimately, comprehensive performance analyses of AI-driven systems confirm that they significantly optimize enterprise IT support, improving both operational capacity and service delivery [13].

III. METHODOLOGY

A. Architectural Framework and Layered Design

The proposed system introduces an intelligent, automated approach to IT support operations by utilizing Artificial Intelligence (AI) and Natural Language Processing (NLP).

To ensure high scalability, flexibility, and ease of maintenance, the architecture follows a highly modular and layered structure. The system is fundamentally divided into four main operational tiers, starting with the User Interaction Layer, which provides the primary communication channels, such as web portals, chatbots, and email interfaces, for users to submit their technical queries. Below this sits the AI Processing Layer, which is responsible for converting raw user text into structured, actionable commands using a robust NLP engine, specialized intent recognition modules, and comprehensive dialogue management. The Application and Integration Layer acts as the bridge, enabling smooth communication between the AI agent and the existing IT infrastructure through specialized automation engines and integration APIs. Finally, the Data Storage and Learning Layer supports ongoing intelligent decision-making by securely housing the knowledge base, interaction databases, and machine learning models that continuously update using historical data and user feedback. This data flow is demonstrated in Fig. 1.

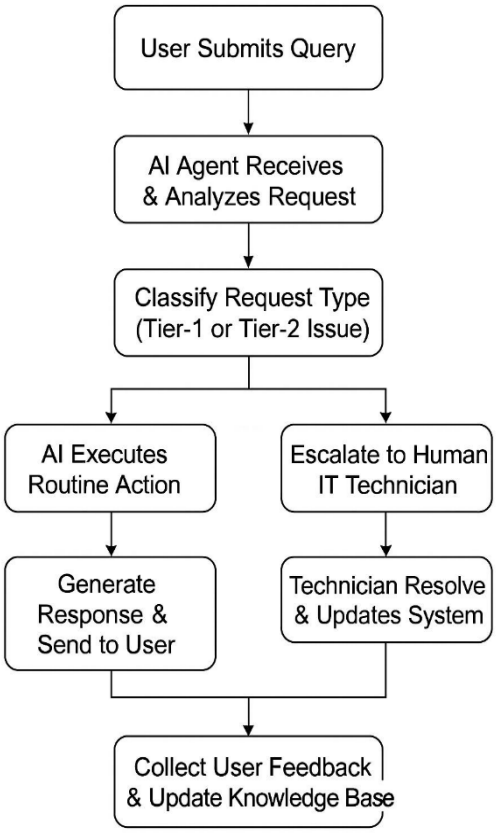

Fig. 1Workflow Diagram of the AI Support System

B. Core AI Processing and GPT-5 Integration

At the core of the AI Processing Layer, the system employs GPT-5 as its central reasoning engine, allowing the platform to autonomously interpret complex user requests, diagnose technical issues, and execute necessary corrective actions through structured tool calls. To guarantee high precision and factual accuracy in its responses, GPT-5 operates in strict conjunction with a Retrieval-Augmented Generation (RAG) system. This critical integration enables the model to connect dynamically with a vector database, allowing it to access a real-time enterprise knowledge base and retrieve highly relevant, company-specific troubleshooting data before formulating a response to the user. To manage these complex interactions, an Agent Orchestrator coordinates tasks across the various modules, ensuring that every user query undergoes rigorous validation, logical reasoning, and appropriate action selection before any scripts are executed.

©IJRASET: All Rights are Reserved

C. Workflow Orchestration and Automation Execution

The operational workflow is initiated the moment a user submits a query through the chatbot or web portal, immediately prompting the NLP engine to process the text and accurately identify the underlying user intent. Based on this intent, the AI agent searches the established knowledge base for existing solutions or directly triggers the application layer to execute specific automation scripts. For routine tasks, the automation engine is programmed to execute predefined actions directly, such as running password reset scripts via an Active Directory integration or initiating software deployments. A critical safeguard within this workflow is the dedicated escalation module, designed to handle any issues that exceed the AI's defined scope or confidence threshold. If a query remains unresolved by the automated systems, the platform automatically forwards the request to a human IT technician, ensuring a highly efficient handover by seamlessly providing a detailed context summary of the entire automated interaction. The architecture of this system is as shown in Fig. 2.

Fig. 2System Architecture Diagram

D. System Modeling and Interaction Protocols

To rigorously define the system's software structure, functional requirements, and complex runtime behavior, Unified Modeling Language (UML) diagrams were heavily utilized throughout the design and planning phases. The generated Use-Case models clearly delineate the functional services offered by the AI support system while mapping out the specific interaction boundaries between end-users, the automated chatbot agent, human technicians, and external infrastructure systems. Furthermore, detailed sequence diagrams were developed to track specific runtime interactions and message sequences, such as the comprehensive password reset flow. This modeled sequence explicitly illustrates the strict order of operations, showcasing how the chatbot parses the password reset intent, queries the knowledge base for organizational policy checks, commands the automation engine to interact securely with Active Directory, and ultimately either delivers a temporary password to the user or creates a support ticket in the ticketing system for human intervention upon failure as seen in Fig. 3.

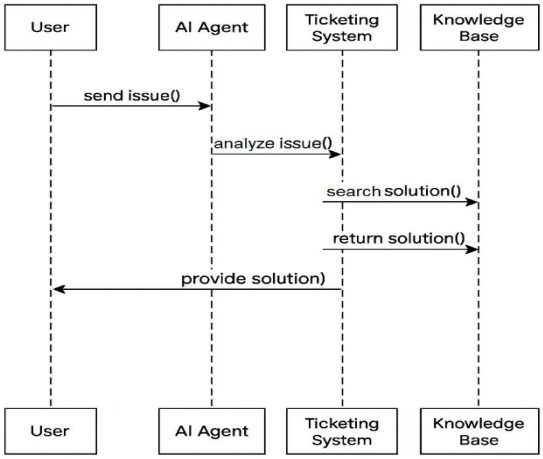

Fig. 3Sequence Diagram for Password Reset Flow

IV. IMPLEMENTATION

A. Development Environment and Hardware Specifications

The physical deployment and development of the AI-driven IT support system required specific hardware parameters to ensure efficient model training, rapid data retrieval, and overall operational stability. The primary system was developed within an environment utilizing an Intel Core i5 processor, or an equivalent processing unit, supported by eight gigabytes of random-access memory and a 240-gigabyte hard disk drive. Continuous network connectivity, which is crucial for backend API integrations and external system communications, was maintained via a standard 10/100 Mbps Ethernet connection. Depending on the specific scale of the machine learning model training required for deployment, an optional Graphics Processing Unit (GPU) could be utilized to accelerate processing times. The foundational operating system for this development and deployment environment offered structural flexibility, supporting either Windows versions 10 or 11, or Linux distributions such as Ubuntu 20.04 and later iterations.

B. Core Software and Artificial Intelligence Frameworks

To construct the core reasoning and processing modules, Python version 3.8 or higher served as the primary programming language, selected specifically for its extensive support for artificial intelligence and enterprise integration. The critical natural language processing capabilities and machine learning functions were developed utilizing industry-standard frameworks, including TensorFlow or PyTorch, operating alongside specialized linguistic libraries such as spaCy and the Natural Language Toolkit (NLTK). These advanced frameworks empowered the system's processing layer to accurately parse conversational user text, recognize underlying contexts, and extract actionable technical intents.

For the user-facing interaction layer, the frontend web and chatbot interfaces were constructed using foundational web technologies including HTML, Cascading Style Sheets (CSS), and JavaScript. The corresponding backend logic, dialogue routing, and gateway management were handled by robust web frameworks such as Flask or Django. Furthermore, persistent data management—encompassing the secure storage of user queries, detailed system logs, the active knowledge base, and continuous training data—was managed through scalable database management systems, relying on MySQL, PostgreSQL, or MongoDB architectures.

C. System Integration and Security Deployment

A highly critical phase of the implementation involved seamlessly connecting the standalone AI reasoning agent to the broader, existing enterprise IT infrastructure. This technical integration was achieved through the extensive use of REST APIs, JSON data formatting, and Webhooks, which authorized the system's application layer to actively communicate with external ticketing platforms, monitoring systems, and directory services.

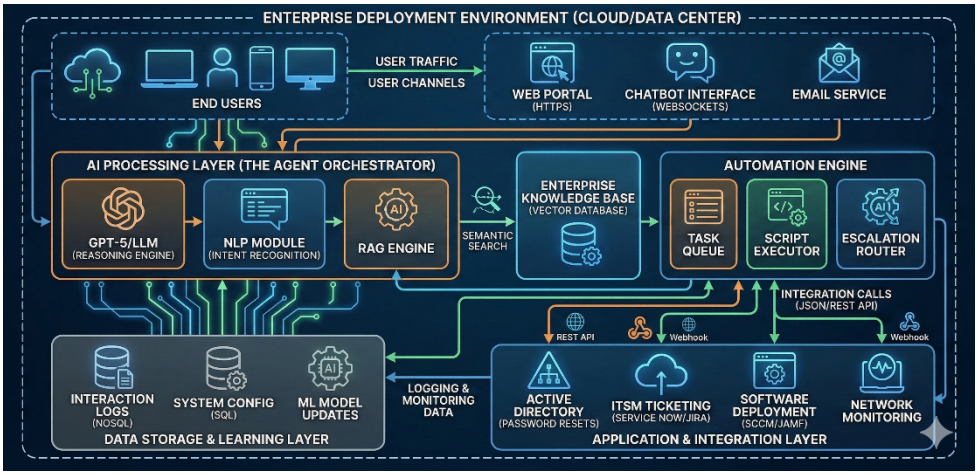

Fig. 4Application Integration and Deployment Architecture

Throughout the project, the software development lifecycle was strictly managed using Git and GitHub for comprehensive source code version control, while Integrated Development Environments (IDEs) such as Visual Studio Code and PyCharm provided the necessary debugging and coding interfaces.

To achieve highly scalable deployment and secure application containerization, the architecture utilized Docker, with broader cloud hosting and virtualization capabilities provided by platforms like Amazon Web Services (AWS) or Microsoft Azure. Finally, to guarantee that all automated support actions and user interactions remained secure against unauthorized access, the final implementation incorporated SSL certificates and robust authentication modules. These security measures are strictly enforced to verify user identities, particularly before the automation engine executes sensitive operations such as automated password modifications or secure account unlocks. This entire deployment architecture is seen above in Fig. 4.

V. RESULTS AND DISCUSSION

A. Functional Evaluation and Capabilities

The proposed system, IT Support Using AI Agent, was implemented and thoroughly evaluated to verify its functional capabilities, operational efficiency, and overall user interaction quality. The final deployment successfully integrated multiple core components, including the Natural Language Processing (NLP) module, automated execution scripts, and backend integrations with both ticketing systems and infrastructure management tools. Functionally, the developed artificial intelligence agent proved capable of autonomously handling a wide variety of routine IT support requests. Through direct integration with Active Directory, the system successfully executed user password resets and account unlocks without human oversight. Furthermore, the agent reliably managed software installation and update requests using automated scripts, alongside executing basic troubleshooting tasks for network diagnostics, printer setups, and system configurations. When interacting with users through the chatbot interface, the NLP engine consistently identified user intent to provide immediate resolutions. Crucially, for unsupported or highly complex queries, the system flawlessly executed ticket creation and seamlessly escalated the issue to a human technician, ensuring that complete conversational context logs were attached to the help-desk ticket.

B. Quantitative Performance Metrics

To quantitatively assess the effectiveness of the AI agent, performance was analyzed using standard IT service-support metrics. The observed results given in table 1 indicate a massive improvement in operational speed, with the AI agent achieving an average response time of just 1.8 seconds to initial user queries. By autonomously handling Tier-1 requests, the system drastically reduced the average issue resolution time by 65 percent when compared directly to traditional, manual support workflows.

The underlying artificial intelligence demonstrated robust comprehension, achieving a 92 percent accuracy rate in correctly identifying user intent during initial interactions. Consequently, this high accuracy translated into an impressive automation success rate, with 88 percent of all submitted routine tasks being fully completed without requiring any human intervention. User reception of the automated system was overwhelmingly positive, culminating in a user satisfaction score of 4.6 out of 5 based on post-interaction feedback surveys. Ultimately, these metrics demonstrate that the AI agent significantly reduces response and resolution times while preserving high task completion accuracy.

TABLE I
QUANTITATIVE PERFORMANCE METRICS

Metric	Description	Observed Result
Average Response Time	Time taken to respond to user query	1.8 seconds
Issue Resolution Time	Average time to resolve Tier-1 requests	Reduced by 65% compared to manual support
Accuracy of Intent Detection	Correctly identified user intent	92%
Automation Success Rate +1	Tasks completed without human intervention +1	88%
User Satisfaction Score	Based on post-interaction feedback	4.6/5

C. Qualitative Outcomes and User Experience

In addition to quantitative measurements, pilot testing revealed several significant qualitative improvements to the enterprise IT environment. The deployment immediately provided 24/7 availability, ensuring users received uninterrupted technical support outside of standard business hours. This continuous, autonomous service directly resulted in a heavily reduced workload for the human IT staff, who reported a 40 percent reduction in the volume of repetitive support tickets assigned to them.

The AI agent also exhibited strong continuous learning capabilities, actively improving its knowledge base and response accuracy through continuous feedback loops.

The user experience was further validated through an analysis of chatbot interaction logs, which illustrated the system's ability to navigate secure workflows. For instance, sample logs demonstrated the agent securely guiding a user through a forgotten password scenario by requesting username confirmation before securely dispatching a password reset link to a registered email address. Finally, when complex issues did arise, the escalation pathways to human support were observed to be smooth, immediate, and contextually complete, preventing user frustration and ensuring continuity of care.

VI. CONCLUSION

A. Fulfillment of Operational Objectives

The implementation of the IT Support Using AI Agent has successfully addressed the primary challenges inherent in traditional, human-dependent IT service models. By effectively automating repetitive Tier-1 tasks, such as password resets and software installations, the system significantly reduces the necessity for manual intervention in routine daily operations. The comprehensive output analysis confirms that the AI-based system achieves its intended objectives, establishing a smarter and more cost-efficient technical support environment. Consequently, human IT staff are liberated from time-consuming, repetitive inquiries, allowing organizations to redirect their human expertise toward complex, high-value strategic functions and advanced technical problem-solving.

B. Enhancement of User Experience and Scalability

Beyond strict operational efficiency, this AI-driven approach fundamentally transforms the end-user support experience. The deployment successfully ensures 24/7 availability, eliminating the traditional constraints of standard business hours and drastically minimizing user downtime. Through the advanced integration of natural language processing and intelligent intent recognition, the frontend chatbot interface delivers immediate and accurate resolutions that directly boost overall employee productivity and user satisfaction. Furthermore, the system's architecture guarantees that whenever a user's query exceeds the automated scope or confidence threshold, a seamless escalation to a human technician occurs. Because this hand-off includes the full conversational context, it guarantees continuity of care, perfectly bridging the gap between automated speed and specialized human expertise.

C. Future Outlook and Enterprise Viability

Ultimately, this project demonstrates that an autonomous, self-learning IT support agent is not only technically feasible but highly advantageous for modern digital organizations. The developed system continuously improves its diagnostic accuracy and operational effectiveness over time by autonomously learning from user interactions and updating its central knowledge base. This inherent self-learning capability, combined with a robust and modular architectural design, proves that the system possesses the critical reliability, scalability, and adaptability required for large-scale enterprise deployment. As enterprise IT infrastructures continue to grow in scale and complexity, the deep integration of intelligent AI agents into IT service management will remain a critical driver for sustainable, proactive, and resilient operations.
