Behavioural Similarity between Marshall Stability and Indirect Tensile Strength Values for DBM Grade-2 using VG-30, VG-40 and CRMB-55 Grade Binder with RAP

Er. Madanjee Kumar[1], Er. Ajay Kumar Duggal[2]

[1]M.E. Scholar, [2]Associate Professor, Department of Civil Engineering, National Institute of Technical Teachers Training and Research, Chandigarh

Abstract: This research investigates the similarities between Marshall Stability and Indirect Tensile Strength (ITS) values for Dense Bituminous Macadam (DBM) Grade 2 mixes using VG-30, VG-40, and CRMB-55 grade binders, incorporating varying proportions of Recycled Asphalt Pavement (RAP). Virgin and modified mixes were prepared with RAP content ranging from 25% to 35% and bitumen content from 4.5% to 4.95 % .Marshall properties which includes stability, air voids, density, voids in mineral aggregate (VMA), and flow values were determined to establish optimal binder and RAP proportions for durable and sustainable pavements. For virgin mixes, VG-30,VG-40 and CRMB-55 grade binders exhibited optimal performance at 4.65% bitumen, achieving maximum stability values of 12.83 kN ,14.69 kN and 14.95kN respectively. Modified mixes with 25% RAP showed peak stability values of 14.40 kN, 14.90 kN, and 14.69 kN for VG-30, VG-40, and CRMB-55 binders, respectively, at optimal bitumen contents. Air voids minimized to below 4.34%, ensuring compactness, while flow values remained within permissible limits.

At 30% RAP, VG-40 and CRMB-55 binders delivered superior performance with stability values of 15.24 kN and 15.29 kN, respectively. For mix with 35% RAP, VG-40 achieved maximum stability of 14.94 kN, while CRMB-55 demonstrated balanced results with a stability of 14.35 kN and optimal deformation resistance. Across all mixes, air voids reduced significantly, and densities remained consistent, ensuring structural integrity. The results demonstrate that incorporating RAP improves mix performance while promoting sustainability. VG-40 and CRMB-55 binders consistently outperformed VG-30, particularly at higher RAP contents, suggesting their suitability for durable and resilient pavement construction. This study provides a comprehensive understanding of the relationship between Marshall Stability and ITS values in DBM Grade 2 mixes, facilitating informed material selection for sustainable infrastructure.

ITS follows the same trend as Marshall Stability, with CRMB-55 showing the highest values at 4.65% binder content (0.83 N/mm², 14.95 kN), followed by VG-40 and VG-30 for conventional Mix. For 25% RAP, VG-40 had the highest stability (14.90 kN), while CRMB-55 had the highest ITS (0.87 N/mm²). With 30% RAP, CRMB-55 exhibited superior stability (15.29 kN) and ITS (0.87 N/mm²). At 35% RAP, VG-40 had the highest stability (14.94 kN), while CRMB-55 led in ITS (0.85 N/mm²).

Keywords: Marshall Stability, Indirect Tensile Strength (ITS), Dense Bituminous Macadam (DBM), Recycled Asphalt Pavement (RAP), VG-30 Binder, VG-40 Binder, CRMB-55 Binder, Bituminous Mix, Sustainability, Pavement Durability.

I. INTRODUCTION

Dense Bituminous Macadam (DBM) is a high-quality road construction material widely used in flexible pavements for highways and other heavily trafficked areas. As a crucial intermediate layer in pavement design, DBM provides structural strength, durability, and resistance to deformation under repeated traffic loads. Its formulation typically includes coarse aggregates, fine aggregates, filler, and a bituminous binder, carefully proportioned to achieve optimal performance.

The increasing demand for durable and cost-effective road infrastructure has led to significant advancements in DBM composition, production, and application methods. DBM plays a vital role in ensuring long-lasting pavement life by withstanding environmental stresses, including temperature variations and moisture infiltration. Moreover, its ability to distribute vehicular loads uniformly to the underlying layers minimizes pavement distress and enhances overall performance.

This Research paper explores various aspects of Dense Bituminous Macadam to show behavioral similarities between Marshall stability which is design parameter and ITS value which show the ability of mix to resist tensile force. The study also investigates the impact of innovative additives, modified binders, and sustainable practices on DBM's durability. By addressing these factors, this research aims to contribute to the development of more reliable and sustainable road construction techniques.

II. NEED AND SCOPE OF STUDY

A. Need For Study

Road transportation plays a vital role in meeting growing transportation demands, requiring both new road construction and improvements to existing infrastructure. While various agents and filler materials have been examined for Marshall Stability and Indirect Tensile Strength (ITS), no comparative research has been conducted. The Marshall Stability Test involves compressive loading, while the ITS test uses indirect tensile loading. Understanding any impact of ITS on Marshall Stability is crucial. This study aims to explore behavioural similarities between Marshall Stability and ITS values for DBM Grade-2 mixes using different grades of bitumen, CRMB-55, and recycled materials, highlighting the applicability of the ITS test for bituminous mixes.

B. Scope And Objectives Of Present Study

This research assess the functionality and characteristics of bituminous mixes through Marshall Stability and ITS tests. The study evaluates the engineering properties of DBM by analysing both tests on the same specimen samples.

This research has the potential to contribute to the development of environmentally friendly road construction practices, addressing issues like binder drainage and tensile strength in recycled material-based DBM. The findings can guide the industry toward more sustainable and durable asphalt solutions.

The main objectives of the present study are:
1) To determine the optimum binder content by Marshall method for control mix for DBM prepared with and without RAP using VG-30, VG-40 and CRMB-55 Grade Binder
2) To determine I.T.S. value of DBM mix at various binder content with and without RAP and ascertain if any similarity exist between Marshall stability and I.T.S Value using VG-30, VG-40 and CRMB-55 Binder.
3) To determine the optimum amount of RAP that can be added in DBM mix.
4) To determine the effect of employing RAP in DBM on the Marshall Stability Value and I.T.S. value.

III. MATERIAL PROPERTIES EVALUATION

A. Aggregates

Aggregates of size 26.5 mm, 19 mm, and 10 mm ,stone dust and RAP were used . The material used satisfied all general requirement as per MORT&H (5th revision) and IRC: SP: 79-2023. The aggregates were collected from the nearby road construction site. The tests which have been done on aggregates are displayed in

Table 1: Physical Properties of Coarse and Fine Aggregates including RAP

Physical properties	26.5mm	19mm	RAP	Required values as per MORTH 5th revision
Specific Gravity	2.62	2.64	2.69	2.6-2.8
Elongation index (%)	11.1	10.7	10.4	Max 30%
Flakiness index (%)	9.2	10.4	9.0	(E.I. + F.I.)
Impact value (%)	20.5	21.0	20.3	Max 24%
Water absorption (%)	0.40	0.50	0.54	Max 2%
Stripping value (%)	2-3	2-3	2-3	< 5%

B. Binder

In this research, VG-30, VG-40 & CRMB-55 is used. To determine the physical characteristics of bitumen, different tests are performed in accordance with IS: 73-2013 & IS 15462:2004 shown in Table 2.

Table 2: Properties of Viscous Grade Bitumen

Properties	VG-30 Grade		VG-40 Grade		Test Method

C. Mineral Filler

Stone dust has been used as the mineral filler in the DBM mix, with the replacement for hydrated lime . It was procured from nearby site in Chandigarh.

IV. EXPERIMENTAL INVESTIGATIONS

A. Aggregate Gradation

To achieve the right blend, different sized aggregates such as 26.5mm,19mm,10mm and filler, are employed. Aggregates weighing 4000g were collected for sieve analysis. To find the specific percentages of different sized aggregates to be employed, the aggregate gradation is carried out using Rothfuch's Method, which confirms to the upper and lower limitations stated as per MoRTH table 500-07.

Table *4* shows grading of aggregate for controlled mix and mix with varying percentage of RAP.

Table 4:Grading of aggregate for DBM

IS Sieve Size	% passing 26.5mm	% passing 19mm	% passing 10mm	% passing SD	% passing RAP	Grading of Mix				% passing required
						Control Mix	Mix with 25% RAP	Mix with 30% RAP	Mix with 35% RAP

B. DBM MIX Design

The mix design was carried out using the Marshall Stability Test to determine the optimum binder content, RAP replacement percentage, ensuring maximum stability values. The design also adhered to other Marshall parameters. The mix was designed to meet the specifications outlined in MoRTH Table 500-11: DBM Mix Requirements.

The samples are prepared in accordance with ASTM D6926: Standard Practice for Preparation of DBM Specimens Using Marshall Apparatus. 75 blows are required on each face of the specimen for DBM mixes. Table 5 shows the proportion of 26.5mm, 19mm, 10mm, Filler and RAP for different DBM mix..

Table 5: Proportion of 26.5mm, 19mm, 10mm, Filler and RAP for different DBM mix.

Size of Aggregate	Ratio of Mixing of aggregate in percent			
	Control Mix	Mix with 25% RAP	Mix with 30% RAP	Mix with 35% RAP
26.5mm	10	20	19	17
19mm	23	16	15	14
10 mm	30	17	15	14
Filler	37	22	21	20
RAP	-	25	30	35

1) Conventional DBM Mix

The Marshall Stability test was carried out in the lab to determine the ideal binder content and stability for conventional DBM mix. Samples were prepared with minimum bitumen of 4.50% and subsequently with an increment of 0.15% and going up to 4.95%.for viscous binder VG-30, VG-40 and Modified Binder CRMB-55.Table 6 displays the Marshall Properties for Conventional DBM Mix with different binder content. Figure 1,Figure 1, Figure 3, Figure 4 and Figure 5 display the variation of various Marshall Parameters i.e., Marshall stability, density, flow value, Voids in Minerals aggregate (VMA) and air void content vs Bitumen Content. Based on experimental data the ideal bitumen concentration for a Conventional DBM mix was determined to be 4.65% for Virgin binder as well as for modified binder.

2) DBM Mix with different proportion of RAP

The incorporation of Reclaimed Asphalt Pavement (RAP) into DBM mixes was evaluated based on Marshall properties. RAP dosage levels were varied across 25%, 30%, and 35%. The range of bitumen content was taken 4.50%,4.65% and 4.80 % which is one below and one above the Optimum Binder Content obtained from Conventional Mix. The gradation corresponding to these RAP percentages was as previously discussed in

Table *4*.Experimental investigations revealed that the Conventional mixes with VG-30 ,VG-40 and CRMB-55 achieved maximum stability at 4.65% bitumen content, with values of 12.83 kN ,14.69 kN,and 14.95 kN respectively. Modified mixes with 25% RAP ,VG-40 and CRMB-55 binders showed stability values of 14.90 kN and 14.69 kN. At 30% RAP, VG-40 and CRMB-55 outperformed VG-30, achieving 15.24 kN and 15.29 kN, respectively. At 35% RAP, stability for VG-40 reduced to (14.94 kN), while for CRMB-55 reduced to (14.35 kN) The results of these assessments are summarized in Table 7,Table 8 and Table 9 respectively and the corresponding graphical representations are illustrated in Figure 6 to Figure 20 for Marshall Stability ,Density, Flow Value, VMA and Air Void with respect to Bitumen.

V. RESULTS AND DISCUSSION

A. Test Result For Control Mix

1) VG-30: The mix showed optimal performance at 4.65% bitumen content with a stability of 12.83 kN, density of 2.36 g/cc, and air voids reduced to 3.20%. The lowest flow value of 3.18 mm was observed, ensuring durability, stability, and deformation resistance.

2) VG-40: The DBM Grade 2 mix achieved peak performance at 4.65% bitumen content, with a stability of 14.69 kN, density of 2.33 g/cc, and air voids of 4.17%. The flow value was minimized to 3.42 mm, highlighting durability and resistance to deformation.

3) CRMB-55: Maximum performance was observed at 4.65% bitumen, achieving stability of 14.95 kN, density of 2.34 g/cc, air voids of 3.61 %, and a flow value of 3.32 mm, ensuring durability and strength.

4) ITS: ITS follows the Marshall Stability trend, with CRMB-55 showing the highest ITS (0.83 N/mm²), followed by VG-40 (0.80 N/mm²) and VG-30 (0.70 N/mm²) at 4.65% binder.

B. Test Result For Modified Mix Using 25 % Rap

1) VG-30: The mix exhibited optimal performance with a stability of 14.40 kN, density of 2.35 g/cc, air voids of 4.34%, and a flow value of 3.42 mm at 4.5% bitumen content.

2) VG-40: The mix achieved peak performance at 4.65% bitumen content, with stability of 14.90 kN, density of 2.37 g/cc, air voids of 3.45%, and a flow value of 3.54 mm.

3) CRMB-55: Strong performance was observed at 4.5% bitumen, achieving stability of 14.69 kN, density of 2.34 g/cc, air voids of 4.20%, and a flow value of 3.16 mm.

4) ITS: ITS values were highest for CRMB-55 (0.87 N/mm²), followed by VG-40 (0.86 N/mm²) and VG-30 (0.80 N/mm²) at 4.65% for CRMB-55 and VG-40 and at 4.50% for VG-30 binder

C. Test Result For Modified Dbm Mix Using 30% Rap

1) VG-30: At 4.8% bitumen content, the mix demonstrated stability of 12.83 kN, density of 2.35 g/cc, air voids of 3.88%, and a flow value of 3.17 mm.

2) VG-40: Optimal results were achieved at 4.65% bitumen content, with stability of 15.24 kN, density of 2.345 g/cc, air voids of 4.39%, and a flow value of 3.71 mm.

3) CRMB-55: The mix achieved excellent performance at 4.65% bitumen content, with stability of 15.29 kN, density of 2.34 g/cc, air voids of 4.41%, and a flow value of 3.23 mm.

4) ITS: ITS values were also highest for CRMB-55 (0.87 N/mm²), followed by VG-40 (0.85 N/mm²) and VG-30 (0.74 N/mm²), all at 4.65% binder.

Volume 13 Issue II Feb 2025- Available at www.ijraset.com

D. Test Result For Modified Dbm Using 35% Rap
1) VG-30: The mix displayed robust performance at 4.65% bitumen content, with stability of 13.06 kN, density of 2.36 g/cc, air voids of 3.34%, and a flow value of 3.34 mm.
2) VG-40: At 4.65% bitumen content, the mix achieved stability of 14.94 kN, density of 2.35 g/cc, air voids of 4.14%, and a flow value of 2.8 mm, showcasing superior mechanical performance.
3) CRMB-55: The mix indicated strong performance at 4.65% bitumen content, with stability of 14.35 kN, density of 2.357 g/cc, air voids of 4.02%, and a flow value of 3.44 mm.
4) ITS: ITS values were highest for CRMB-55 (0.85 N/mm²), followed by VG-40 (0.81 N/mm²) and VG-30 (0.78 N/mm²) at 4.65% binder

VI. CONCLUSIONS

The study revealed notable differences and improvements in performance between various binders (VG-30, VG-40, and CRMB-55) and RAP proportions (25%, 30%, and 35%). For virgin mixes, CRMB-55 demonstrated superior performance with a maximum stability of 14.95 kN at 4.65% bitumen content, representing a 16.5% improvement over VG-30, which achieved 12.83 kN. At 25% RAP, VG-40 and CRMB-55 exhibited similar stability values of 14.90 kN and 14.69 kN, respectively, with VG-40 showing a slight improvement of 1.4% over CRMB-55. At 30% RAP, CRMB-55 marginally outperformed VG-40 with stability values of 15.29 kN and 15.24 kN, respectively, indicating a negligible variation of 0.3%. Both binders significantly outperformed VG-30, which exhibited an estimated stability of around 14.5 kN, translating to an improvement of 5% or more for the other two binders.

At 35% RAP, VG-40 achieved the highest stability value of 14.94 kN, outperforming CRMB-55 by 4.1%, which provided a stability value of 14.35 kN. Although CRMB-55 showed slightly lower stability at this level, it demonstrated superior deformation resistance, making it a balanced choice for mixes with higher RAP content. The findings indicate that stability generally improves with increasing RAP content up to 30%, while a slight decrease is observed at 35%. VG-40 consistently outperformed VG-30 across all RAP levels, while CRMB-55 provided competitive stability and additional deformation resistance, especially at higher RAP proportions. Overall, incorporating RAP up to 35% is feasible and sustainable without compromising pavement performance, provided appropriate binders like VG-40 or CRMB-55 are used.

This study examines the impact of binder type and RAP content on the mechanical properties of DBM Grade 2 mixes. ITS follows the same trend as Marshall Stability, with CRMB-55 showing the highest values at 4.65% binder content (0.83 N/mm², 14.95 kN), followed by VG-40 and VG-30. For 25% RAP, VG-40 had the highest stability (14.90 kN), while CRMB-55 had the highest ITS (0.87 N/mm²). With 30% RAP, CRMB-55 exhibited superior stability (15.29 kN) and ITS (0.87 N/mm²). At 35% RAP, VG-40 had the highest stability (14.94 kN), while CRMB-55 led in ITS (0.85 N/mm²). These results highlight CRMB-55's strength and VG-40's stability, emphasizing their influence on sustainable pavement design

VII. LIMITATIONS AND FUTURE SCOPE

This study offers valuable insights into the correlation between Marshall Stability and ITS values for DBM Grade-2 mixes with RAP but has limitations. Testing was conducted under controlled laboratory conditions, not accounting for real-world variables like temperature, moisture, and traffic. RAP content was limited to 25%, 30%, and 35%, excluding higher proportions, while only VG-30, VG-40, and CRMB-55 binders were evaluated, leaving out options like polymer-modified binders. The focus on short-term performance metrics overlooked long-term factors like aging, fatigue resistance, and cracking. Additionally, uniform RAP properties were assumed, ignoring variability in RAP sources, binder content, and aggregate gradation. Addressing these gaps in future research can enhance understanding and promote durable, sustainable RAP-incorporated DBM mixes.

This study establishes a foundation for further exploration of the correlation between Marshall Stability and ITS values for DBM Grade-2 mixes with RAP. Future research can validate findings through field trials under real-world conditions, considering traffic loads, environmental factors, and aging effects. Investigating higher RAP proportions (>35%), advanced binders (e.g., polymer-modified or bio-based), and extended performance metrics like fatigue resistance, rutting, and moisture susceptibility will provide comprehensive insights. Assessing environmental and economic impacts, such as energy savings, carbon footprint, and cost-effectiveness, alongside optimization models, can ensure efficient and sustainable mix designs. These efforts will support broader RAP adoption, enhancing sustainability and durability in road construction.
