Bloodlink: Blood Bank on Web

Mr. Om Limbhore, Mr. Prathamesh Landge, Mr. Ritesh Kharat, Mr. Tejas Khawal, Mr. Prashant Kolhe, Prof. Afrin Sheikh.
Savitribai Phule Pune University, Department of Engineering Science KJ College of Engineering and Management Research Pune, India

Abstract: ***This paper presents the development and implementation of a web-based blood donation platform designed to streamline the connection between blood donors and recipients. The system enables user-friendly registration, donor search based on location and blood type, real-time blood request posting, and administrative management of donation data. Built using HTML, CSS, JavaScript for the frontend, Node.js for the backend, and MongoDB for the database, the platform emphasizes responsiveness, data security, and efficient communication. This solution addresses key limitations of traditional blood bank systems such as manual coordination, delayed responses, and lack of transparency. The platform aims to promote voluntary donation, enhance emergency responsiveness, and improve the overall efficiency of blood distribution.***
Index Terms: Blood Donation, transfusion, centralized system, conventional methods, automated system, analytical processing.

I. INTRODUCTION

This project is a web-based Blood Donation Platform designed to simplify and promote the process of blood donation by connecting donors and recipients through a user-friendly online system. Developed using HTML and CSS for the front-end interface, Java for the backend logic, and MongoDB as the database, this platform aims to bridge the gap between those who need blood and those who are willing to donate it.

The platform allows users to register as either donors or recipients, providing essential details such as name, blood group, contact number, city, and address. Once logged in, users can search for donors or recipients in their city, view profiles, and get in touch directly. A clean and responsive UI, combined with efficient backend processing, ensures smooth navigation and real-time data access.

By leveraging MongoDB's flexible data structure, the system handles large volumes of user information efficiently, ensuring quick data retrieval and updates. The backend, built in Java, manages user authentication, data handling, and business logic, offering a secure and reliable environment for all transactions.

This platform not only supports emergency blood requests but also helps build a community of active donors, contributing to a faster and more organized blood donation process.

II. LITERATURE REVIEW

Sr.no	Name of Authar	Title of paper	Claimed by author	Our Finding
1	**Manvir Kaur**	A Web-based Blood Bank System for Managing Records of Donors and Receipts	The Online Blood Management System is a platform that plays an important role in one's life during an emergency. It is a platform where anyone can register himself or herself as a donor on the website.	In this paper we fount out that,There is no desease mentioned while registring and in terms and condition section we have to mention it.We've also maken an advancement that we have to mention the terms and conditons very precisely.
2	**Mohammed Y. Esmail**	Computerized Central Blood Bank Management System (CCBBMS)	Computerized central blood bank management system CCBBMS is a system that used to manage and control all activities in blood bank departments. The systems save all donor records, blood information, testing results, distribution of blood to hospitals, discarding of bad blood and create medical reports.	Here the author only mentioned that they've maken this software on for the computer use.There is no web link.It can only be used in Computers of the Blood Bank.
3	**Neetu Mittal**	Blood bank information system using Android application.	The proposed Android is more user-friendly and easy to use as compared to existing blood bank apps. In existing interfaces their statistics shows how many units of required blood group are available. The reports section shows the month in which blood group are being distributed and received.	Here we've noticed that the application is slower as compare to website and we can access website from anywhere.
4	**Soumya Sen**	Blood bank Database storage.	An integrated framework to manage end to end blood management process has been devised with front end web modules and back end databases. Special focus has been given to localized blood donation campaign management.	Here we have seen that there is a need of creating seprate Database for the system & we can avoid these things by maintaining records for a shorter time.

III. KEY FEATURES OF BLOOD BANK SYSTEM

The WOMEN application is designed for safety and empowerment, beginning with a secure login system where users authenticate via mobile number or email. Once logged in, the app accesses the user's live location using GPS, allowing real-time tracking that can be shared with trusted contacts or emergency services.

Key features include an SOS button for instant alerts, route tracking for travel safety, emergency contact integration, and live location sharing. Additional tools may include nearby help centre locators, safety tips, and in-app communication with guardians or authorities. All data is encrypted to ensure user privacy and security throughout the experience.

IV. METHODOLOGY

1) System Design and Planning

The development of the blood donation platform began with requirements gathering and system analysis. Key stakeholders, including potential donors, recipients, and healthcare administrators, were consulted to identify the primary features needed: user registration, donor search by location and blood type, real-time request posting, and administrative data management. Based on these requirements, a modular and scalable system architecture was designed.

2) Frontend Development

The frontend of the platform was built using HTML, CSS, and JavaScript to ensure an interactive and responsive user interface. Special attention was given to mobile responsiveness and user experience (UX) to accommodate a wide range of users. Features such as registration forms, search filters, and blood request submission forms were developed using modern web development practices.

3) Backend Development

The backend was implemented using Node.js to handle server-side operations, API integrations, authentication, and real-time communication. Express.js, a Node.js framework, was utilized to simplify routing and server management. The backend was responsible for processing user data, managing sessions, and enabling secure communication between the client-side and the database.

4) Database Management

MongoDB, a NoSQL database, was employed for storing user profiles, donation histories, blood requests, and administrative data. The database schema was designed to support quick retrieval of donor information based on blood type and location, ensuring efficient query performance. Security measures such as encryption and secure password storage were implemented to protect user data.

5) Real-Time Features

Real-time functionalities, including instant blood request postings and donor notifications, were integrated using WebSocket protocols and relevant Node.js libraries. This ensured immediate communication between donors and recipients during emergency situations.

6) Security and Privacy Measures

To ensure data security and privacy, industry best practices such as HTTPS communication, encrypted user authentication (e.g., JWT tokens), and database access control were adopted. Regular security testing was conducted to identify and mitigate vulnerabilities.

7) Testing and Deployment

The platform underwent extensive unit testing, integration testing, and user acceptance testing (UAT) to ensure functionality, reliability, and usability. Upon successful testing, the application was deployed on a scalable cloud platform to ensure high availability and performance

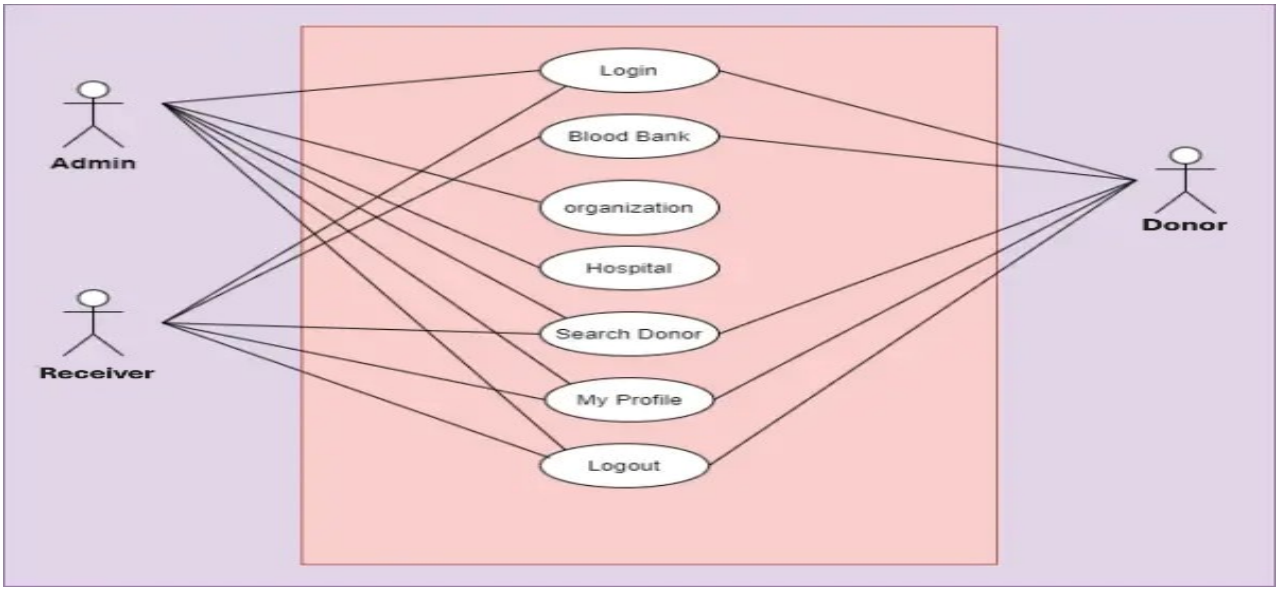

Figure.1 Visual Representation of the application

V. CONCLUSION

The Web-Based Blood Donation Platform, developed with HTML, CSS, Java, and MongoDB, offers a user-friendly and efficient solution to connect blood donors and recipients. Featuring secure authentication, role selection, and detailed profiles, the platform enables real-time, city-based searches through a clean, interactive interface. Java handles backend logic and database interaction, while MongoDB efficiently manages user data. The black-and-red design highlights urgency and health. Overall, the platform addresses a critical healthcare need and is scalable for future enhancements like SMS alerts and blood camp notifications.
