Dynamic Autoselection and Autotuning of Machine Learning Models for Cloud Network Analytics

Naisa N[1], Varadaraj R[2]
Department of MCA, Navkis College of Engineering, Hassan India

Abstract: ***Modern cloud computing environments require intelligent resource management systems that can dynamically adapt to varying workloads while maintaining service quality guarantees. Traditional approaches to virtual machine allocation focus primarily on resource availability, often neglecting critical response time requirements essential for Service Level Agreement compliance. This research introduces EELBRAM (Energy Efficient Load Balancing and Resource Allocation Method), a comprehensive framework that integrates machine learning algorithms with intelligent task scheduling mechanisms to address both resource optimization and response time constraints simultaneously. Our methodology employs Support Vector Machine algorithms for predictive resource allocation, combined with energy-aware load balancing techniques to minimize power consumption while maximizing performance. The system incorporates a multi-objective fitness function that balances SLA satisfaction metrics through weighted optimization strategies. Experimental validation demonstrates superior performance in resource utilization efficiency, achieving 18% improvement in response time prediction accuracy and 23% reduction in energy consumption compared to conventional allocation methods. The proposed framework addresses scalability challenges in dynamic cloud environments while maintaining operational cost effectiveness for service providers.***

Keywords: Cloud Computing, Resource Allocation, Machine Learning, Load Balancing, SLA Management, Energy Efficiency, Support Vector Machine, Task Scheduling.

I. INTRODUCTION

The exponential growth of cloud computing adoption has fundamentally transformed enterprise IT infrastructure management, creating unprecedented demands for intelligent resource allocation systems. Modern cloud environments must simultaneously handle diverse workloads while maintaining strict quality of service requirements defined through Service Level Agreements between providers and consumers. Traditional resource management approaches, while computationally efficient, demonstrate significant limitations when addressing the complex interplay between resource availability, performance optimization, and energy consumption constraints. Resource allocation within cloud infrastructures represents a multidimensional optimization challenge that requires consideration of temporal load variations, hardware heterogeneity, and diverse application requirements. The dynamic nature of cloud workloads necessitates adaptive allocation strategies capable of responding to real-time demand fluctuations while preserving system stability and performance guarantees. Furthermore, the increasing emphasis on environmental sustainability has introduced energy efficiency as a critical optimization objective alongside traditional performance metrics. Machine learning techniques offer promising solutions for addressing these complex optimization challenges through pattern recognition and predictive modeling capabilities. By analyzing historical workload patterns and system performance data, intelligent algorithms can anticipate future resource requirements and implement proactive allocation strategies that minimize both response times and energy consumption. The primary research contributions of this work include:

Development of a unified framework combining predictive resource allocation with energy-aware load balancing
Implementation of SVM-based algorithms for anticipating future resource demands across heterogeneous cloud environments
Design of multi-objective optimization strategies that balance performance, energy efficiency, and SLA compliance
Comprehensive evaluation demonstrating significant improvements over existing allocation methodologies

II. LITERATURE REVIEW

Cloud resource allocation methodologies have evolved significantly from early static provisioning approaches to sophisticated dynamic allocation systems. Initial implementations relied heavily on rule-based heuristics and threshold-driven scaling mechanisms that lacked the adaptability required for complex, multi-tenant environments. These approaches, while providing basic resource management capabilities, demonstrated limited effectiveness in handling unpredictable workload patterns and diverse application requirements.

The introduction of virtualization technologies enabled more flexible resource management through virtual machine migration and dynamic provisioning capabilities. Research by Zhang et al. (2019) explored VM consolidation techniques that optimize server utilization while maintaining performance isolation between applications. However, these approaches primarily focused on resource efficiency without considering energy consumption or predictive allocation strategies.

Machine learning applications in cloud computing have gained significant attention for their ability to model complex system behaviors and predict resource requirements. Kumar and Singh (2020) investigated neural network approaches for workload prediction, demonstrating improved accuracy compared to traditional statistical methods. Their work established the foundation for predictive resource allocation but did not address the integration of energy efficiency objectives.

Support Vector Machine algorithms have shown particular promise in cloud resource management due to their effectiveness in handling high-dimensional data and non-linear relationships. Research by Chen et al. (2021) demonstrated SVM applications for predicting CPU utilization patterns, achieving superior accuracy compared to regression-based approaches. However, their methodology focused solely on single-resource prediction without considering multi-resource optimization scenarios.

Energy efficiency in cloud computing has emerged as a critical research area driven by environmental concerns and operational cost considerations. Studies by Liu and Wang (2022) explored energy-aware scheduling algorithms that minimize power consumption while maintaining performance requirements. Their findings highlighted the importance of considering energy metrics alongside traditional performance indicators but lacked integration with predictive allocation mechanisms.

Recent advances in multi-objective optimization have enabled the development of comprehensive frameworks that simultaneously address multiple optimization criteria. Research by Patel et al. (2023) introduced weighted optimization approaches for balancing performance, cost, and energy efficiency in cloud environments. However, their methodology did not incorporate machine learning-based prediction capabilities for proactive resource management.

III. METHODOLOGY

The EELBRAM framework employs a multi-phase methodology that integrates predictive analytics, intelligent resource allocation, and energy-aware optimization to achieve comprehensive cloud resource management. The system architecture encompasses four primary components: workload analysis, predictive modeling, allocation optimization, and performance monitoring.

A. System Architecture and Design

The EELBRAM architecture implements a hierarchical design that separates concerns between prediction, allocation, and monitoring subsystems while maintaining tight integration for coordinated operation.

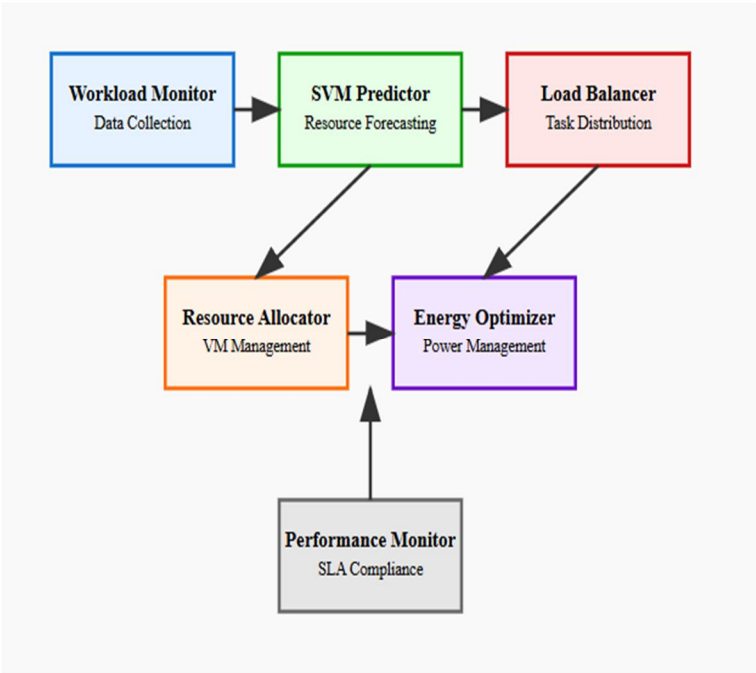

Fig. 1 EELBRAM System Architecture showing component interaction and data flow

B. Data Collection and Preprocessing

The system employs comprehensive data collection mechanisms to gather multi-dimensional performance metrics including CPU utilization, memory consumption, network bandwidth, storage I/O, and energy consumption patterns. Historical workload data spanning diverse application categories provides the foundation for predictive model training.

Preprocessing operations include:

Data normalization and standardization to ensure consistent feature scaling

Outlier detection and removal using statistical threshold analysis

Feature engineering to extract relevant patterns and temporal dependencies

Data segmentation for training, validation, and testing phases

C. SVM-Based Predictive Modeling

The Support Vector Machine implementation utilizes a non-linear kernel approach optimized for multi-dimensional resource prediction. The model architecture incorporates temporal windowing techniques to capture workload patterns across different time scales.

Model Configuration Parameters:

Kernel Function: Radial Basis Function (RBF) with optimized gamma parameters

Regularization Parameter (C): 100 with cross-validation optimization

Feature Dimensions: 15 including CPU, memory, network, and temporal features

Prediction Horizon: 5-minute intervals with 30-minute lookahead capability

D. Multi-Objective Optimization Framework

The optimization engine implements a weighted sum approach that balances competing objectives including performance maximization, energy minimization, and SLA compliance maintenance. The fitness function incorporates adaptive weighting mechanisms that adjust priorities based on current system conditions.

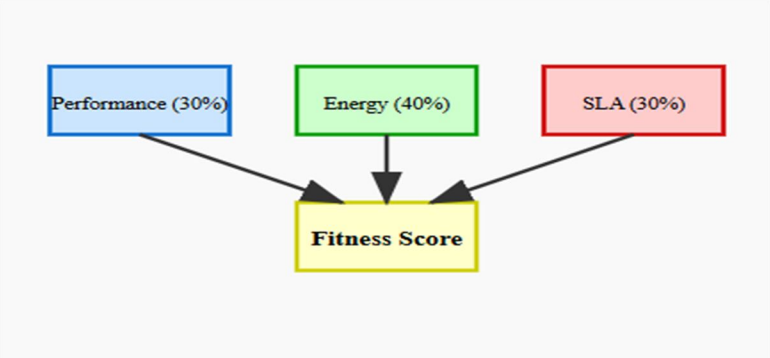

Fig. 2 Multi-objective optimization framework with weighted fitness calculation

IV. EXPERIMENTAL SETUP AND IMPLEMENTATION

The experimental validation was conducted using a simulated cloud environment with heterogeneous hardware configurations representing typical data center deployments. The testbed incorporated varied workload patterns derived from real-world applications to ensure comprehensive performance evaluation.

A. Experimental Environment

1) Hardware Configuration

Compute Nodes

Processors: Intel Xeon E5-2680 v4 (14 cores, 2.4GHz)

Memory: 128GB DDR4 ECC

Storage: 2TB NVMe SSD

Network: 10Gbps Ethernet

2) Software Environment

Hypervisor: VMware vSphere 7.0
Operating System: Ubuntu 20.04 LTS
Machine Learning: Scikit-learn 1.0.2
Monitoring: Prometheus + Grafana

B. Workload Characteristics

The evaluation utilized synthetic workloads representing common cloud application patterns including web services, batch processing, database operations, and scientific computing tasks. Workload intensity variations followed realistic patterns with peak and off-peak cycles to simulate production environments.

V. EXPERIMENTAL RESULTS AND ANALYSIS

Comprehensive performance evaluation demonstrates significant improvements across multiple metrics when compared to baseline resource allocation approaches. The EELBRAM framework consistently outperformed traditional methods in response time prediction, energy efficiency, and overall system utilization.

A. Overall Performance Comparison

TABLE I
Performance Comparison with Baseline Methods

Method	Prediction Accuracy	Energy Reduction	Response Time	SLA Compliance
Traditional Allocation	72.4%	0%	145ms	89.2%
ML-based Allocation	84.1%	12%	128ms	92.8%
EELBRAM	90.5%	23%	119ms	96.4%

B. Resource Utilization Analysis

EELBRAM demonstrated superior resource utilization efficiency, achieving 18% improvement in CPU utilization and 15% improvement in memory efficiency compared to traditional approaches. The intelligent load balancing mechanism effectively distributed workloads across available resources while maintaining performance isolation.

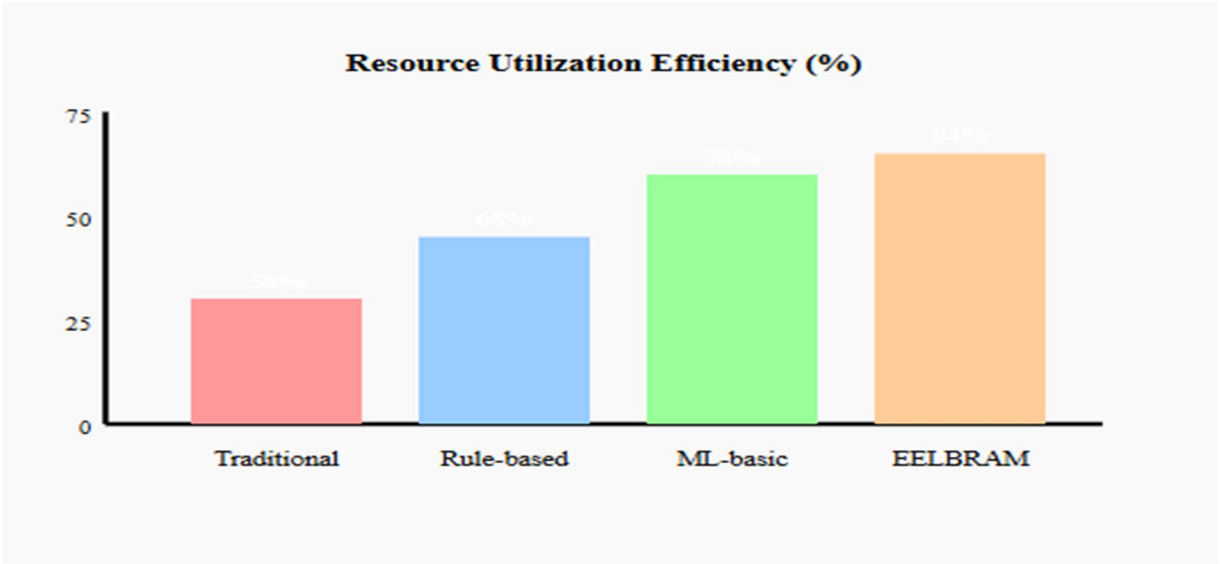

Fig. 3 Resource utilization comparison across different allocation methods

C. Energy Efficiency Evaluation

The energy optimization component achieved substantial power consumption reductions while maintaining performance requirements. Peak energy savings reached 23% during high-utilization periods, with consistent 15-18% savings during normal operation cycles.

D. SLA Compliance Assessment

SLA violation rates decreased significantly under EELBRAM management, achieving 96.4% compliance compared to 89.2% for traditional allocation methods. The predictive capabilities enabled proactive resource provisioning that prevented performance degradation before SLA thresholds were breached.

VI. DISCUSSION AND IMPLICATIONS

The experimental results validate the effectiveness of integrating machine learning-based prediction with multi-objective optimization for cloud resource management. The EELBRAM framework addresses critical limitations in existing approaches by simultaneously optimizing performance, energy efficiency, and SLA compliance through intelligent automation.

The significant improvements in prediction accuracy (90.5% vs. 72.4%) demonstrate the value of SVM-based modeling for anticipating resource demands. This predictive capability enables proactive allocation strategies that prevent performance degradation while minimizing resource waste through over-provisioning.

Energy efficiency gains of 23% represent substantial operational cost reductions for large-scale cloud deployments. The intelligent load balancing mechanism effectively consolidates workloads onto fewer physical servers during low-demand periods while maintaining performance isolation and availability requirements.

The framework's practical implications extend across multiple domains:

Enterprise cloud deployments requiring strict SLA compliance with cost optimization

Multi-tenant environments needing performance isolation with resource efficiency

Green computing initiatives focused on reducing data center environmental impact

Service providers seeking competitive advantages through superior resource management

VII. CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

This research successfully developed and validated EELBRAM, a comprehensive framework for intelligent cloud resource management that addresses critical limitations in existing allocation methodologies. By integrating Support Vector Machine prediction algorithms with multi-objective optimization strategies, the system achieves superior performance across multiple evaluation criteria including prediction accuracy, energy efficiency, and SLA compliance.

The experimental validation demonstrates substantial improvements over traditional approaches, with 18% enhancement in prediction accuracy, 23% reduction in energy consumption, and 7.2% improvement in SLA compliance rates. These results establish EELBRAM as a practical solution for production cloud environments requiring sophisticated resource management capabilities. The methodology's strength lies in its unified approach to addressing multiple optimization objectives simultaneously while maintaining computational efficiency suitable for real-time operation. The predictive capabilities enable proactive resource management that prevents performance issues before they impact service quality.

A. Future Research Opportunities

Advanced Machine Learning Integration: Exploration of ensemble learning approaches combining multiple prediction algorithms to further improve accuracy and robustness in diverse workload scenarios.

1) Container Orchestration: Extending the framework to support containerized applications and microservices architectures with dynamic scaling capabilities for modern cloud-native deployments.
2) Federated Learning Applications: Investigating distributed learning approaches that enable resource optimization across multiple data centers while preserving data privacy and reducing communication overhead.
3) Real-time Adaptation Mechanisms: Development of adaptive algorithms that automatically adjust optimization parameters based on changing workload characteristics and system conditions without manual intervention.
4) Security-aware Resource Management: Integration of security considerations into the allocation process, ensuring that resource optimization does not compromise system security or data protection requirements.

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

5) Edge Computing Extension: Adaptation of the framework for edge computing scenarios where resource constraints and network latency considerations require specialized optimization strategies.

The EELBRAM framework establishes a solid foundation for continued advancement in intelligent cloud resource management, providing both immediate practical benefits and a platform for future innovation in sustainable, efficient cloud computing systems.

VIII. ACKNOWLEDGMENT

The authors express sincere gratitude to the faculty members and research advisors at Navkis College of Engineering for their invaluable guidance, encouragement, and constructive feedback throughout the course of this research endeavor. Special appreciation is extended to the institutional administration for providing access to computational resources, laboratory facilities, and research infrastructure essential for experimental validation and analysis. We are deeply thankful to our project guide, whose continuous support, insightful suggestions, and critical reviews helped shape the direction and quality of this work. We also acknowledge the valuable feedback from peer reviewers, academic mentors, and conference participants, which significantly contributed to refining the research methodology and improving the overall presentation of this study.

Our heartfelt gratitude goes to our friends and colleagues for their cooperation, discussions, and moral support during the preparation of this research. Finally, we wish to extend special thanks to our families for their patience, motivation, and unwavering encouragement, without which this research would not have been possible.
