Elevating Forestry Prediction: A Study on Machine Learning Model for Plantations Survival Rate Analysis

Akshaya Rathore
DFO Guna Forest Division

Abstract: ***This paper details the development and preliminary findings of a machine learning model designed to predict the survival rate of plantations. Drawing data from official sources, various vegetation indices were used as features for the predictive model. Initial results show potential, despite certain limitations, suggesting avenues for further enhancement and application.***

I. INTRODUCTION

Plantations play a significant role in environmental conservation and economic sustenance. Predicting their survival rates becomes essential for sustainable development and forest management. With advancements in remote sensing and machine learning, this research aims to develop a predictive model using satellite imagery indices and the Gradient Boosted Trees algorithm to determine the survival rate of plantations.

II. STUDY AREA

The study area includes plantations done by MP Forest Department in East Chhindwara Division from 2015 to 2018.

III. METHODOLOGY

A. *Data Collection*

The primary source for the research data was the Madhya Pradesh Forest Department's official portal www.mpforest.gov.in, from which the Plantation Survival Report and KMLs of plantations were extracted.

B. Data Processing

The KMLs are then checked for their geometrical validity and then KMLs of plantations of same year are merged to have shapefile containing geometries of all plantations of same year .

C. Calculations

Satellite imagery indices, including NDVI (Normalized Difference Vegetation Index), MCARI (Modified Chlorophyll Absorption Ratio Index), SAVI (Soil-Adjusted Vegetation Index), MSI (Moisture Stress Index), and NDWI (Normalized Difference Water Index), were considered. These indices provide crucial insights into vegetation health, soil moisture, chlorophyll content, and water stress, making them imperative for analyzing plantation survival.

Using Google Earth Engine, the slope of these indices was determined over a five-year span to track and understand growth trends. The code takes input as shapefile containing geometries of all plantations of particular year and output as CSV file containing slope trends of all indices and plantation ID.

```
// Improved cloud and shadow masking using the SCL band.
var maskCloudsAndShadows = function(image) {
  var SCL = image.select('SCL');
  var mask = SCL.neq(3).and(SCL.neq(8)).and(SCL.neq(9)).and(SCL.neq(10)).and(SCL.neq(2));
  return image.updateMask(mask);
};

// Function to convert system:time_start metadata to a band.
var addTimeBand = function(image) {
  // Convert milliseconds from Unix epoch to years since 2000 for improved numerical stability
  var yearsSince2000 = image.metadata('system:time_start').divide(1000 * 60 * 60 * 24 * 365.25).subtract(2000);
  return image.addBands(yearsSince2000.rename('time'));
};

// Load Sentinel-2 Surface Reflectance data.
var collection = ee.ImageCollection('COPERNICUS/S2_SR')
    .filterDate('2016-01-01', '2022-01-01')

D. Model Creation

Our dataset, housed within Google Sheets, encompassed 112 unique plantation records, each denoted by a Plantation ID. Each record detailed the slopes of satellite-derived indices, serving as predictive features for plantation survival rates. Using the "Simple ML for Sheets" extension, we streamlined machine learning directly within the spreadsheet, bypassing intricate coding processes.

For the modelling:

1) *Data Labelling:* Plantation survival status after 5 years, extracted from official reports, was our target variable.
2) *Feature Selection:* Continuous slope values from indices like NDVI and SAVI became our independent variables, suitable for regression models.
3) *Model Training & Evaluation:* We employed the Gradient Boosted Trees algorithm for its robustness in handling vast datasets. The extension facilitated automatic data partitioning for training and validation, subsequently evaluating the model's accuracy on unseen data.

Model Evaluation

```
Number of predictions (without weights): 111
Number of predictions (with weights): 111
Task: REGRESSION
Label: SURVIVAL RATE

RMSE: 9.99285 CI95[X2][8.83349 11.5053]
Default RMSE: : 16.5915
```

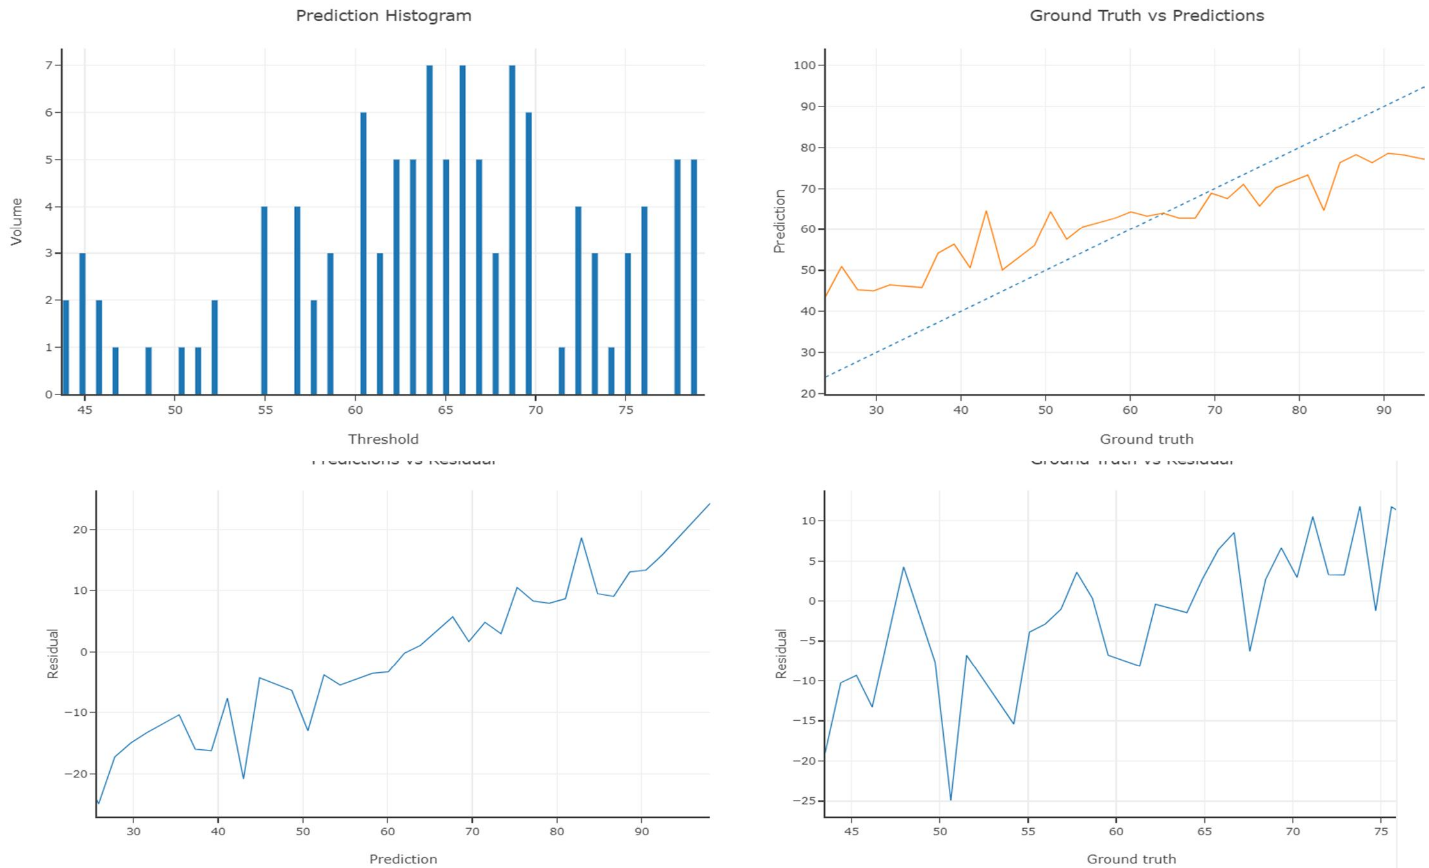

Fig.6 Model Evaluation Report

IV. RESULTS AND INTERPRETATION

Of the 112 plantations analysed, the model accurately predicted the survival of 91. The overall accuracy stood at 81.25%. However, the research encountered a limitation in the form of the database's restricted scope, sourced from just one forest division spanning four years only2015 to2018. Consequently, predictions for plantations with reduced survival rates showed significant errors.

V. DISCUSSION

The model, in its present iteration, holds potential, even if the accuracy isn't at an optimal level. Its primary value lies in assisting field officers in identifying plantations at risk. By flagging potential failures, proactive measures can be initiated to mitigate issues. For future iterations, it's imperative to diversify and expand the dataset. Incorporating additional indices and geometric features could further enhance the model's predictive capabilities.

VI. FUTURE WORK

1) Augmenting the dataset is a priority, ensuring diverse data sources to refine the model further.
2) New indices and geometric parameters, especially features like land surface temperature, will be considered in the updated model.
3) Plans to automate the entire model are underway using platforms such as Google Colab, making the process more user-friendly.
