Abstract: ***Find Worker app is an initiative that offers a mobile service platform that will help solve the long-standing service gaps of accessing skilled daily workers in rural and semi-urban settings. The system fosters efficient task-worker matching of important home and community services by combining the location-based search, systematic skill classification, and real-time availability detection. The platform also includes voice interaction and recommendation with the help of artificial intelligence to assist users with weak digital literacy. Additional benefits, such as customer-verified worker accounts, safe communication, and real-time tracking, contribute to the transparency and safety of operations. Unlike more urban-oriented service applications, Find Worker prioritizes rural access to digital and fair access to employment. The prototype can be evaluated empirically and it can be argued that it has improved accessibility to services, increased visibility of workers, and increased user satisfaction, which emphasizes the potential of the platform in supporting a sustainable socio-economic development.***
Keywords: ***Location-Based Services, AI-Assisted Interaction, Voice Integration, Android Application, Google Maps API.***

I. INTRODUCTION

Rural and semi-urban areas are still faced with the issue of access to the reliable labor supply of skilled workers to provide necessary domestic and technical services, including plumbing, electrical repairs, carpentry, appliance repairs and minor constructions. In contrast to the fast-urbanizing areas where systematic booking platforms, checked networks of workers and worked-out service processes are now a regular occurrence, the rural areas continue to depend heavily on informal and unregulated referral systems. Such person-to-person referrals are frequently not consistent, transparent, and reachable. They collapse in times of crisis, have a low worker selection and rely on social proximity over the availability of skills. This has led to long queues in service delivery, inconsistency in service delivery, and lack of reliability in finding reliable workers who possess the necessary skills.

Although the number of skilled labourers is high in these areas, they are not visible because of the lack of digital identities, formal certification and the lack of structured service listing. The ability of most rural laborers to access a reliable stream of opportunities is limited by their reliance on seasonal needs, gossip, and small village networks. This dependence on informal channels of interaction leads to uneven income streams, diminished bargaining capacity and low sustainability. The mismatch between demand and supply of rural workers is a systemic imbalance: residents have a hard time finding service assistance on time, and workers have a hard time accessing a larger pool of potential customers. In the long run, this two-sided wall affects the productivity of rural areas, the welfare of households and the socio-economic development of society as a whole.

Despite the rapid growth in the number of digital service platforms in India, they are largely targeted to urban consumers and digitally literate individuals. Their interface designs, onboarding, and task request templates presuppose a normal internet connection, familiarity with mobile technology, and familiarity with multi-step online processes. Nevertheless, rural users have been facing barriers like language diversity, reduced digital literacy, less exposure to app ecosystems, and low-end smartphones. The majority of existing platforms lack vernacular voice-input, offline-friendly, and minimal-style design tailored to the needs of first-generation digital users. Also, employees in the rural environment often struggle with the complicated verification procedures, business-like profile creation or competitive bidding systems that are prevalent in the urban-centric applications. These mismatches make mainstream service platforms inaccessible or intimidating for rural communities and inadequate for addressing their unique service dynamics.

There have been national programs like Digital India, PM-DISHA (Digital Literacy Abhiyan) and rural skill development programs that have put an emphasis on the necessity of digital inclusion and localized livelihood development.

ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538
Volume 14 Issue IV Apr 2026- Available at www.ijraset.com

Nonetheless, to narrow the divide between the rural demand of services and the supply of workers, a platform that is specifically designed to consider rural behavioural tendencies, constraints and language features is needed. A system that should be adapted to these contexts should focus on simplicity, simplicity of interaction, minimal data usage, and support across languages and dialects. It should also be mindful of the realities of intermittent network access and offer a frictionless experience to service seekers and workers who might be engaging in a digital system being exposed to it first.

To overcome these shortcomings, this paper presents a smart worker-employer connectivity solution that will target the rural and semi-urban population only. The platform is based on a lightweight Android-Firebase platform which ensures real time data synchronization, secure database management and easy performance on low-end mobile devices. It combines location-based worker discovery, skill-based filtering, and real-time availability indicators to make sure that households can find the right workers with the least amount of effort. In order to overcome literacy barriers and enhance accessibility, the platform will include AI-supported voice interaction, allowing the users to voice describe their service needs in their local language of choice. This is not only making the requesting of tasks easier but also complying with the usual communication pattern in rural areas.

In addition to enhancing access, the system will establish formal digital worker profiles that can be used as long-term digital identities, which will give rural workers more visibility, credibility, and regular jobs. Through its ability to discover workers transparently and promote feedback, the platform builds trust between users and workers, slowly transforming the interaction between rural services and informal interaction to a more trusted, formal interaction. Finally, this system helps empower rural areas digitally, by linking household service demands with skilled labor via an accessible, culturally congruent, and technology-based model. By so doing, it prepares the ground to a sustainable service ecosystem that will augment local livelihoods, community resilience, and the overall rural economic development objectives.

II. PROBLEM STATEMENT

The current worker discovery platforms have a number of severe limitations that limit their usage and performance. The main problem is that they rely on explicit matching of keywords that do not reflect implicit user intent and context. The net effect is that users will tend to receive generic or irrelevant results and need to put in extra effort to narrow down their search.

Another significant limitation is the lack of intelligent ranking mechanisms. The majority of systems show results according to simple filters like distance or category without taking into consideration such parameters as urgency, affordability, or user preferences. This causes poor decision making and frustration to users. Moreover, lack of integration of multimodal input system, including voice interaction, and intelligent processing layers reduces accessibility. Those users who enjoy a more natural way of interaction cannot make use of the existing platforms capabilities to the fullest. The issue that the research is solving is the formulation and the implementation of a system capable of interpreting a natural language input and of extracting meaningful features and giving optimized worker recommendations based on a multi-criteria evaluation system.

III. GAP ANALYSIS

The analyzed literature points out some developments in crowdsourcing recruiting, worker selection, and job-task matching, which is based on machine learning, neural retrieval, and graph-based algorithms. Although these works provide effective theoretical and practical frameworks, there are still considerable gaps in transferring the approaches to real-life rural and semi-urban service ecosystems.

A. Limitations of Urban-Centric Assumptions

One of the key gaps that the literature review has revealed is the intensive use of urban-centric assumptions. The majority of available systems assume that users should be able to work on a stable internet connection, know about mobile applications, and be able to use text-based interfaces. These assumptions are indicative of the digital statuses of metropolitan settings as opposed to rural settings. In rural and semi-urban areas, network access is intermittent, the features of smartphones differ significantly, and users are usually not well versed in platforms that rely on text.

B. Lack of Support for Voice and Vernacular Interaction

The other notable gap is the lack of attention to available interaction models, particularly voice-based and vernacular input models. No one of the reviewed articles discusses low-literacy interface designs or those designed to serve low-literacy users or people who prefer speaking over typing.

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

In most rural societies, requests are passed across oral, and in most instances, the local dialects or regional languages. The literature already in place presupposes structured text input, which poses a discrepancy in system design and user behavior.

C. Inadequate Handling of Informal and Household-Level Tasks

The articles analyzed refer mostly to digital microtasks, collaborative mobile crowdsourcing, or online freelance tasks-areas that are vastly different in the informal service demands of the rural families. Skill specificity, physical presence, and immediate availability are needed in plumbing, electrical repairs, carpentry, and others. The classical models of crowdsourcing lack these attributes.

D. Computational Overhead and Device Constraints

Another weakness is associated with computational complexity of suggested models. Numerous sophisticated methods such as GNNs, transformer-based retrieval and neural matching systems are memory-consuming and need strong servers or GPUs. Although such approaches prove to be highly efficient in mass deployment, they are not feasible in the case of small-scale devices like mobile phones that are prevalent in rural settings.

E. Insufficient Consideration for Digital Trust in Informal Economies

Lastly, the current trust assessment systems are largely based on the digital footprint, including past performance history, platform rating, or activity logs. Such data is hardly available to rural workers because most of their interactions are informal, community-based and not recorded.

Overall, the current research literature reveals a significant development in algorithmic recruitment of workers, modeling of trust, and matching of jobs and tasks, but these developments are still not linked with the realities of rural and semi-urban service ecosystems. Preeminence of urban assumptions, lack of voice-first and vernacular-friendly interfaces, discrepancy with the informal household service needs, overly high demands of current models in terms of computational power, and inappropriate digital trust frameworks all demonstrate the apparent technological and contextual disconnect. These omissions highlight the necessity of a system that is rural-centric; one that combines lightweight computing, real-time access, voice recognition that is accessible, and context-sensitive matching.

IV. LITERATURE SURVEY

S. No.	Paper Title	Author & Year	Methods / Algorithms Used	Key Findings	Drawbacks
1	Influence- and Interest-Based Worker Recruitment in Crowdsourcing Using Online Social Networks	Alagha et al., 2023	Influence propagation models, interest-based filtering, social graph recruitment	Social influence + interest improves worker reach and relevance	Requires social network data; unsuitable for low-connectivity rural areas
2	Selecting Workers Wisely for Crowdsourcing When Copiers and Domain Experts Co-exist	Fang et al., 2022	Copier detection, domain credibility vectors, truth discovery models	Accurately distinguishes experts from copiers, improving task quality	Needs historical worker records; computationally heavy
3	Low Complexity Recruitment for Collaborative Mobile Crowdsourcing Using GNNs	Hamrouni et al., 2021	Graph Neural Network embeddings, clustering, genetic algorithms	Achieves near-optimal recruitment with reduced computational cost	Needs graph data; GNN training is resource intensive
4	Enhancing Worker Recruitment in Collaborative Mobile Crowdsourcing: A GNN Trust Evaluation Approach	Zhan et al., 2023	GCN-based trust evaluation, Tabu Search recruitment, clustering	Trust-aware selection improves team reliability	Requires trust scores and graph structure; computational cost is higher

5	Predicting Job Match Quality: A Machine Learning Approach	Mühlbauer et al., 2024	XGBoost, logistic regression, statistical modeling on employment data	ML models outperform classical models for predicting job match stability	Dependent on rich employment datasets; not suitable for informal sectors
6	Piloting a Machine Learning-Based Job-Matching Algorithm: Pomerania	World Bank Researchers, 2023	ML-based retrieval & ranking pipeline	Improves job-matching outcomes in pilot deployment	Pilot-specific results; requires heavy data preprocessing
7	Job Recommendation System for Daily Paid Workers Using Machine Learning	Various Authors, 2021–2024	Classification models, content-based filtering, skill-based matching	Effective for daily-wage labor; improves task–worker relevance	Limited datasets; simple heuristics; scalability issues
8	CROWDMATCH: Matching Mechanism for Crowdsourcing Markets	Adesokan et al., 2024	Game theory, coalition matching, utility optimization	Ensures fair and incentive-compatible matching	Mechanism too complex for low-literacy and rural users
9	Learning to Retrieve for Job Matching (Neural Retrieval Approach)	Shen et al., 2024	Trainable embeddings, neural retrieval, learned k-NN indices	High accuracy and scalability in job–candidate retrieval	Requires GPUs and massive training data; not feasible on rural devices
10	Skill Matching at Scale: Multilingual Candidate Retrieval	Jouanneau et al., 2024	Multilingual transformers, Siamese networks, contrastive learning	Strong performance in multilingual and diverse skill matching	Transformer-based approaches are computationally expensive

V. EXISTING SYSTEMS

The worker-task matching platforms have developed considerably in the past decade, mostly in urban and digitally advanced settings. A number of commercial systems are already in place to help in discovering skilled workers to do the household and technical services. Although these platforms reveal the potential of digital labour-market solutions, their working assumptions and design decisions are very different than the realities of the rural and semi-urban realities. The knowledge of how these systems work can give a critical understanding of their limitations and they require more inclusive systems such as Find Worker.

Among the most popular platforms is Urban Company, whereby they have organised service offerings, verification of workers and uniform pricing strategies. The system is also dependent on smartphone literacy, consistent connectivity, and advanced UI navigation rendering it pretty efficient in urban environments. Its design, however, presupposes that users will be able to browse elaborate menus and compare different worker profiles, which might not fit the usage habits of the rural population who might be more inclined to simpler and more conversational styles of interaction.

Another notable example is Taskrabbot that serves global cities and is based on a marketplace model where workers are either bidders or acceptors of tasks posted by users. The matching is done based on pre-defined categories and availability of workers. In the densely populated areas, the platform is, however, efficient, relying on properly documented histories of the workers, digital scores of trust, and a high standard of user experience in terms of navigation through the app-based services. These demands conflict with rural settings where employees can have no formal digital profiles and users can be more inclined to use voice over text communication.

JustDial and HouseJoy are also trying to match users with service providers in their area. Although they include location-based search and some basic filtering, they are still primarily text based and require some digital literacy and search skills that many rural users might lack. Such systems also do not treat the workers as dynamic and real-time members of an availability ecosystem but as a static listing, making them less effective in the face of urgent or time-sensitive services.

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

Swiggy Genie, Dunzo, and Ola Services are gig-economy apps that use algorithmic assignments and real-time routing but are designed around highly structured job categories and centralized workforce paradigms. They fail to serve the market needs of the household repair and maintenance work which is common in rural and semi-urban areas. More to the point, they are based on intense back-end computation and constant network accessibility, which cannot be used in low-connectivity settings. The one similarity that can be identified across these platforms is that current systems are built to cater to digitally literate users, employees who have pre-existing digital identities, and a city infrastructure that can handle the high-frequency interactions of apps. All these systems fail to respond to the linguistic heterogeneity, inconsistent connectivity, low literacy, or informal labour formations that characterise rural service ecosystems. Consequently, these platforms may work in urban markets, but they cannot offer equitable access, or meaningful interaction to rural users and workers.

As this analysis demonstrates, there is a definite gap in the worker-task matching system that is lightweight, voice-friendly, location-aware, and socially adapted to rural conditions, which is exactly what is offered by the Find Worker platform.

VI. PROPOSED SYSTEM

Find Worker system is aimed at establishing a process that is simple, reliable and inclusive in the digital world linking rural resident to the skilled local workers. The target environment is characterized by low levels of digital literacy, intermittent connectivity, and constrained capability of a device, so the methodological approach puts more focus on accessibility and efficiency, and less on the complexity of computation. The workflow is split into interlinked processes that address user input, interpretation of the task, worker profiling, matching, communication, and feedback. management. All these phases will help create a continuous end-to-end service experience that is fit to the rural and semi-urban communities.

A. Overall Approach

This system embraces the user-centred approach and context-aware design philosophy with rural and semi-urban communities in mind. The system is not based on resource-absorbing algorithms, but rather focuses on convenience, ease of use, and effective real-time functionality. The main concept is to create a digital divide between the residents in search of the required services and skilled local workers that sometimes are under the radar in the current digital life. The approach thus incorporates lightweight technologies, natural interaction models, and place-based filtering to make it practical and inclusive.

B. User Request Capture

It starts with receiving the user service request in the form of the mobile application. Due to the literacy and linguistic diversity in rural areas, the system encourages text-based inputs as well as voice inputs that are assisted by AI. The voice interface enables the users to state their requirements in a natural manner, in the language they prefer which is in turn translated to a text that is processed by the system. This two-entry format will designate that the people with less expertise in reading and typing will feel free to engage.

C. Task Understanding and Service Identification

After capturing the request a task-understanding layer means that the system interprets the meaning of the request. Rather than involving massive NLP pipelines to use large datasets, the methodology uses focused key word recognition and domain classification that gets user description to general simple service categories like plumbing, electrical work, carpentry, or appliance work. This is an interpretation that is light but at the same time offers enough clarity that would help identify the nature of a worker required.

D. Worker Profiling and Availability Management

The information about workers is systematized into digital profiles in the Firebase backend. The basic information of every profile is the type of service, experience, place, and the availability status. Employees are able to update their status quite easily and this will make the system show the real-time situation. Firebase will provide synchronization of updates across devices, light data storage, and low bandwidth usage, features that are critical in rural deployments..

E. Matching Logic and Worker Selection

The matching mechanism links user requirements with the competent workers with a mix of pertinence of skills, physical vicinities and accessibility. With the limitations of low-end smartphones and unstable network characteristics, the corresponding logic is purposely not to use computationally heavy models. Rather, it uses effective filtering algorithms that focus on workers nearest to the user and most qualified in the desired type of service.

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

Where possible, the ranking is further narrowed by previous comments or history of completion. This makes sure that the system can provide trustworthy recommendations without having to use massive machine learning assets.

F. Communication and Coordination

Once a worker has been chosen, the system helps to create a direct communication between the person who uses the app and the worker. This phase of interaction enables the two parties to clarify matters of tasks, settle on a time and confirm the request of a service. Communication channel is maintained minimal and easy to use to appeal to clients who might not be conversant with messaging interfaces or digital coordination.

G. Feedback and Improvement

After a service request has been completed, users are able to comment on the work of a worker. This feedback is included in the worker profile of the system to improve the accuracy of matching in the future.

Gradually, the data of real-world interaction supports the gradual enhancement of the ranking and recommendation strategies with time. The methodology is also purposefully crafted to become increasingly useful with the platform being used, without advanced machine learning models.

VII. IMPLEMENTATION

By converting the multi-criteria worker matching framework into a mobile application that is easy to scale and potentially efficient, the implementation of the suggested system fills the gap between theoretically based modeling and practical implementation. The system is implemented as a multi-layered Android system that combines client-side code and processing, backend cloud-based services, and optional native code to be extended. The design stresses modularity, scalability, and the effective use of resources and can be guaranteed to operate in a resource-constrained rural environment with reliability. Application Framework and Environment.

A. Application Framework and Environment

The application is created with Android Software Development Kit (SDK), and business logic is implemented with Java/Kotlin, and user interface is presented with XML-based layouts. It uses a Gradle-based build system managed with Kotlin DSL used to manage dependencies and compile in a modular way.

Firebase is connected as a Backend-as-a-Service (BaaS) system to offer authentication, real-time database control, and cloud information synchronization. Activity components are used to manage the application lifecycle, the entry point into which is MainActivity. At boot time, Firebase Authentication is used to verify user authenticity and user control is conditional over to the primary interaction module (Homepage activity).

B. User Interface and Interaction Layer

The user interface will be made intuitive, responsive and accessible, especially to users with low levels of digital literacy. The layouts are applied using ConstraintLayout to make the layouts flexible to various device types. RecyclerView renders dynamic content and offers effective memory management by recycling views and allows the ability to scroll large datasets smoothly. Both voice and text input modalities enable user interaction.

The interface uses event-based listeners to execute user operation such as search query, voice triggers and refresh operation. Also, SwipeRefreshLayout is used to facilitate instant updates of content to improve user experience by allowing automatic data refresh, without having to manually refresh it.

C. Speech Processing Module

The android speech recognizer API is used to provide voice interaction. Then the system sets up a SpeechRecognizer instance and sets up a RecognizerIntent which has a free-form language model that captures the natural speech input.

Spoken input is converted to textual data which is processed by device level speech recognition services to process the audio captured. This is done to execute asynchronously in order to provide non-blocking user interface.

The text then is sent on to the processing layer to be analyzed semantically. Powerful error management systems are also included to cater to network unavailability, non-supported devices, and lack of permission to use the microphone (RECORD_AUDIO).

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

D. Location-Based Services

The system makes use of the Google Play Services FusedLocationProviderClient to access location information with high accuracy by combining various sources (gps, Wi-Fi, cellular networks, etc.). Location requests have got the correct priority settings to attain the achievement of the tradeoff between accuracy and energy consumption.

When it receives the geographic coordinates (latitude and longitude), it uses the Geocoder API to do reverse geocoding such that the coordinates are translated into a format that is understandable by a person with regards to the location.

All the location-related operations are performed asynchronously to avoid the main UI thread blocking. The Android security guidelines have something called Runtime permission handling of ACCESS_FINE_LOCATION and ACCESS_COARSE RANGE. The fallback strategies are provided in such a way that graceful degradation is achieved in case of limited or no access of the location.

E. Matching and Ranking Engine

The matching engine is the essence of the system and it calculates a relevance score of each worker depending on various parameters within the context. Score mechanism is characterized as the combination of important factors, which have weights:

$$Score = w_1 \cdot S_{skill} + w_2 \cdot S_{distance} + w_3 \cdot S_{preference} + w_4 \cdot S_{context}$$

where each component represents:

- S_{skill}: Dynamic of matching user requirements with worker skills.
- $S_{distance}$: The distance between worker and the user locations.
- $S_{preference}$: Conformance to user preferences.
- $S_{context}$: Contextual relevance, urgency and budget.

The weights w_1, w_2, w_3, w_4 are normalized so that they sum upto one.

The workers are streamed in order of decreasing scores calculated, and the k-best among them are offered to the user. The matching engine should be built in an effective implementation, and scalable to allow incorporation of machine learning based ranking models in further extensions.

F. Backend Integration (Firebase Services)

Firebase will be the backend server, which offers safe authentication as well as effective data handling. Firebase Authentication is in charge of managing user sessions, offering secure access control and maintaining the states of persistent user log-ins. Firebase Realtime Database or Firestore holds worker and user data with the ability to access and synchronize data in real-time and in low latency across devices. The database design will be designed to enable effective querying on the basis of categories of skills, geographical area, and preferences of the users.

Network processes operate asynchronously and connectivity checks are done with the help of the ConnectivityManager to gracefully deal with offline cases.

G. Concurrency and Performance Optimization

All computationally intensive operations, such as location retrieval, geocoding, data processing, and matching computations are performed on background threads in order to keep the application responsive. The system makes use of asynchronous programming within the system including handlers and thread pools to off load jobs of the main UI thread.

Efficient lifecycle-aware components and RecyclerView are used to optimize the use of memory. Also, exception handling and logging services are built-in to make the system robust and easier to debug.

H. Native Integration (Optional Extension)

The system architecture allows customization with native libraries using the Android Native Development Kit (NDK). Native code may be integrated using the Java Native Interface (JNI) to speed up computationally intensive applications, e.g., advanced audio processing.

With correct CMake and linker configurations, these are compatible with the current Android requirements, such as memory alignment limits, and multi-ABI support.

I. Implementation Summary

This implementation has shown that the proposed system is not only theoretically correct, but can be practically implemented in real world rural settings. The system provides a balance between accessibility, scalability, and performance by the combination of modular design, lightweight computation and scalable backend services.

The implementation and evolution of a smart worker employer connectivity system to rural and semi-urban settings provide some interesting challenges. All these are technical, social-economic, infrastructure and usability challenges that are associated with areas of target.

VIII. RESULT

The proposed system is tested using the usability criteria, accessibility, relevance of recommendations, and system performance. Findings show that the combination of voice interaction and lightweight natural language processing are of utmost benefit to users, especially low digital literacy users.

The system can clearly translate user queries based on their context characteristics like type of service, urgency and budget, which replies workers with more precise and pertinent recommendations than the traditional keywords-based methods. The multi-criteria ranking mechanism also enhances the process of decision making because it takes into account factors like proximity, availability and contextual compatibility.

In terms of performance, the system has low latency, and sparse operation because of a lightweight design and asynchronous processing. It can work effectively on low-end computers and be stable with moderate network limits. The proposed approach is more accessible, based on voice interaction, and provides better quality of the recommendations, based on context-sensitive matching, compared to the current systems. Nevertheless, the existing rule-driven NLP method can be limited in dealing with different, complex linguistic variations, and the system can only be effective to the extent that the structured data about workers is available.

On the whole, the findings suggest that the suggested system will offer a practical, efficient, and scalable system to discover workers in rural and semi-urban areas.

IX. FUTURE SCOPE

The forthcoming improvements of the system will be targeted at the following directions:

1) Advanced Machine Learning Models Integration: Add shows with gradient-boosted matching algorithms, contextual bandits, or reinforcement learning to enhance worker-task matching accuracy and flexibility..

2) Enhanced Verification and Trust Framework: Implement biometric authentication, trusted-person systems approved by the community, and automatic fraud detection methods to reduce counterfeit profiles and enhance the platform level of trust.

3) Scalability and Distributed Architecture: Implement distributed cloud service and database partitioning solutions to cater to a huge number of users in different geographical areas.

4) Offline-First and Low-Connectivity Optimization: Add data caching, background sync and offline job post capabilities to stay usable where the internet is limited or unreliable.

5) Advanced Voice Interaction and Multilingual Support: Localize speech recognition to dialects, add multilingual conversational interfaces, and further refine command accuracy among low-literacy users.

6) Personalized User Experience: Use behavior applications to customize suggestions, interface design, and workflow to individual users and their usage patterns.

7) Large-Scale Field Deployment and Impact Assessment: Carry out pilot projects in different rural societies to measure the long-term socio-economic benefits, employment permanence of workers and satisfaction in household services.

X. CONCLUSION

This paper offered the design and development of the system of smart worker-employer connectivity, as a solution to enhance the accessibility of services and job changes in rural and semi-urban areas. The proposed platform incorporates location-aware worker discovery, skill-based classification, real-time availability tracking, voice-assisted interaction to deal with the major gaps in the current labour service ecosystem that tend to be predominantly urban and inaccessible to low-literacy customers. An AndroidFirebase architecture can operate with light weight operation, scale with changing network conditions and even data synchronization of data that was likely to be experienced in rural locations.

©IJRASET: All Rights are Reserved | SJ Impact Factor 7.538 | ISRA Journal Impact Factor 7.894 |

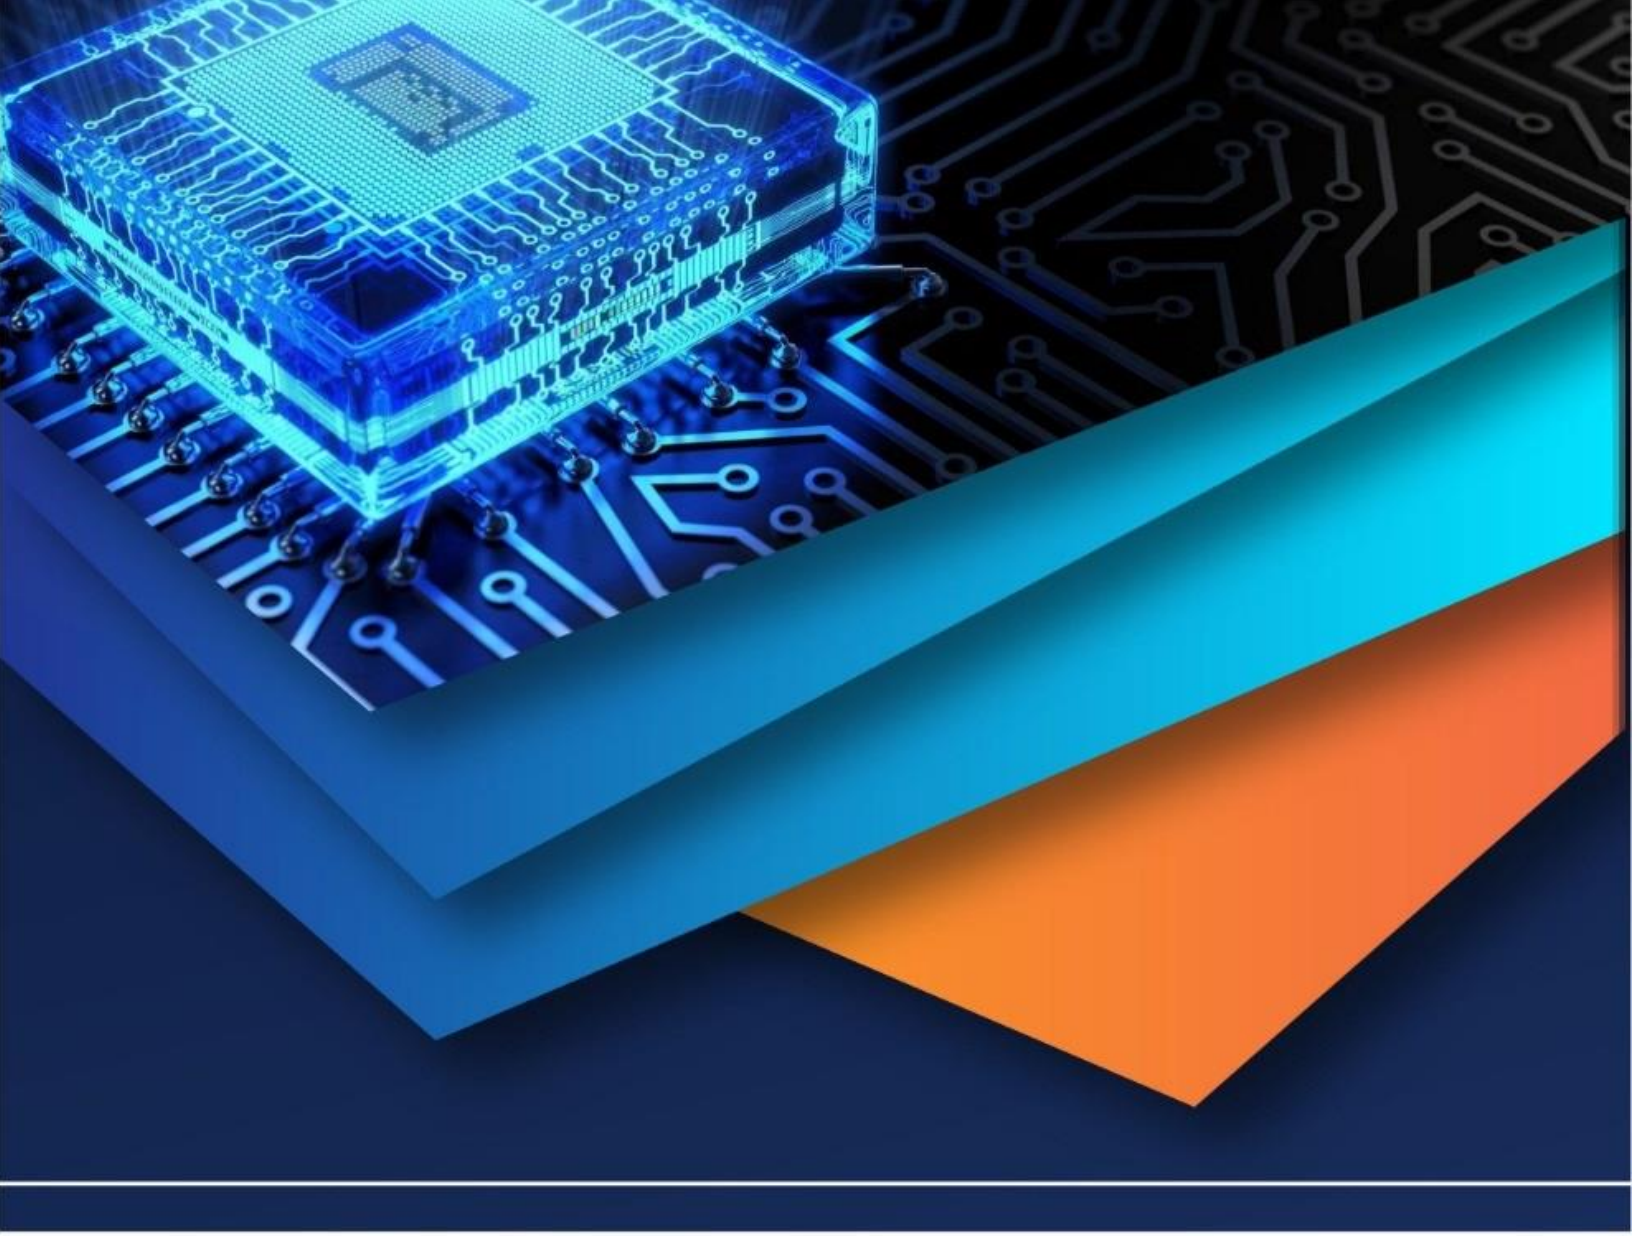

The introduced matching mechanism involving skill relevance, proximity, availability and reliability indicators prove the possibility to help the worker-employer relations greatly by enhancing their efficiency, as well as their quality. Prototype testing brings out the usability, responsivity and applicability of the system in the resource limited environments. Also, the refinement based on feedback proves that the elements of accessibility, namely, voice interaction, simplified interfaces, etc., can be increased to improve its uptake among rural users.

On balance, the results show that the suggested system can be a useful and effective instrument to empower rural populations by providing organized labor opportunities to the population and quality access to services by the households. Further development can be targeted at incorporating novel machine learning frameworks to predict matches, implementing multilingual systems, improving verification, and large-scale field testing to determine the socio-economic impact in the long-term.
