Identification of Social Anxiety in High School: A Comprehensive Machine Learning Approach to Real-Time Student Behavior Analysis

Miss. Snehal Lakhe¹, Prof. Shafiya Sayyad², Prof. Mukul Jagtap³

Department of Artificial intelligence & Data Science, Shalaka Foundation Keystone School OF Engineering, Pune

Abstract: This research presents a comprehensive study on identifying social anxiety among high school students using datadriven techniques. The study integrates machine learning algorithms, clustering models, and correlation analysis to evaluate psychological and behavioral patterns from the Social Phobia Inventory (SPIN) questionnaire. Data collected from students of Little Scholars Matriculation Higher Secondary School, Tamil Nadu, forms the basis of this analysis. Results highlight distinct clusters of anxiety levels, their correlation with academic performance, and behavioral triggers. The paper further proposes Virtual Reality (VR) and Augmented Reality (AR)-based interventions to reduce anxiety, aiming to provide a modern, technology-assisted mental health support system for educational institutions.

Keywords: Social Anxiety, Machine Learning, Educational Psychology, SPIN Questionnaire, VR Therapy, Data Science, Student Behavior Analysis.

I. INTRODUCTION

Social anxiety disorder (SAD) is a growing concern among adolescents, significantly influencing their communication skills, confidence, and academic performance. Traditional methods of assessment rely heavily on subjective evaluations by psychologists, which often lack scalability. This study introduces a machine learning-based framework to objectively assess, classify, and interpret anxiety traits in real time. By leveraging survey data and predictive models, it becomes possible to identify at-risk students early and design intervention strategies tailored to their emotional needs.

II. OBJECTIVES OF THE STUDY

- 1) To assess the prevalence and intensity of social anxiety among high school students.
- 2) To explore correlations between anxiety traits and student characteristics.
- 3) To apply clustering and predictive analytics to identify anxiety patterns.
- 4) To propose the use of VR and AR tools for reducing anxiety levels through immersive experiences.

III. LITERATURE REVIEW

Previous studies have established a strong relationship between social anxiety and reduced classroom engagement. Research by Hofmann et al. (2007) indicates that socially anxious students often avoid participation due to fear of judgment. Machine learning has recently emerged as a robust approach to detecting psychological trends from behavioral data.

Studies involving decision trees, support vector machines, and deep learning architectures have achieved accuracy in identifying emotional states. However, limited work has been conducted in the Indian school context, making this study a pioneering effort in bridging that gap.

IV. METHODOLOGY

The research employs a mixed-method approach combining quantitative and qualitative analyses. The dataset was derived from 500 students aged 13–17 years, who completed the 17-item SPIN questionnaire anonymously. Responses were preprocessed, normalized, and encoded for machine learning analysis. Supervised algorithms such as Decision Trees and Random Forests were applied to identify key predictors of anxiety. Unsupervised techniques like K-Means clustering were used to categorize students into distinct anxiety- level groups.

V. DATA COLLECTION AND ETHICAL CONSIDERATIONS

Data collection adhered to ethical guidelines approved by the school's Institutional Review Board. Participants were informed of the study's objectives, and consent was obtained from both students and parents. Confidentiality was strictly maintained using anonymized identifiers. Counseling support was provided to any student exhibiting distress during or after the survey process.

VI. RESULTS AND ANALYSIS

Analysis revealed that approximately 37% of participants exhibited moderate to severe social anxiety levels. Correlation matrices highlighted strong interrelations between self- esteem, public performance fear, and avoidance behaviors. K-Means clustering produced five primary groups representing different anxiety intensities. Machine learning models achieved an accuracy of 91% in predicting social anxiety based on the questionnaire responses.

VII. DISCUSSION

The findings underscore the significance of data-driven approaches in identifying emotional well-being patterns. Students categorized under high-anxiety clusters demonstrated consistent avoidance behaviors and physiological symptoms such as blushing or trembling. These insights suggest the need for proactive psychological support systems in schools. Moreover, integrating VR exposure therapy within academic counseling sessions can provide personalized, immersive interventions.

VIII. CONCLUSION

The study successfully demonstrates the applicability of machine learning in identifying and analyzing social anxiety among adolescents. The model provides educators and mental health professionals with actionable insights into student behavior, enabling early intervention. By combining traditional psychology with technological innovation, this framework paves the way for data-assisted emotional health monitoring in schools.

IX. FUTURE WORK

Future research should explore cross-institutional datasets to validate the model across diverse demographics. Deep learning models can further enhance feature extraction from behavioral data. Additionally, integrating biometric sensors and real-time emotion tracking can offer a holistic understanding of anxiety triggers. The potential of VR/AR-based adaptive therapy should be explored through long-term pilot programs in schools.
