Impact of Childhood Trauma on Adult Relationships

Akshita Singh¹, Dr. Chaaya Gupta²

¹BA Student, AIBAS, Amity University Uttar Pradesh Lucknow Campus

²Assistant Professor, AIBAS, Amity University Uttar Pradesh

Abstract: *Considering the issue of gender differences, the present study was trying to explore how childhood trauma affects relationships at adulthood. Attachment style is one of the most important psychological traits that determine the functioning of the relationships as it represents the way people establish emotional connections and react to intimacy. The aim of the study included measuring the degree of childhood trauma and its correlation with the patterns of relationships in adulthood and to investigate whether the variables have gender differences. A sample of 50 adults aged 18-30 years was used as the sample and sampled randomly. Childhood Trauma Questionnaire (CTQ) was utilized in order to be able to measure the early adverse experience and Experiences in Close Relationships Scale (ECR) was utilized to measure the attachment styles and relationship dynamics. The independent samples t-test found that there was no significant difference in gender in terms of attachment insecurity but difference in gender was seen in particular aspects of childhood trauma with females reporting more emotional abuse and neglect and males reporting more physical abuse. The analysis of correlation showed that childhood trauma and insecure attachment pattern had a significant positive relationship, which implies a positive correlation between higher levels of trauma and more problems in the relationship. This means that the people who are more exposed to negative situations in early development might have more difficulties with trust, intimacy, and emotional control in adulthood. In general, the results indicate that though the role of childhood trauma in adult relationships is obvious, it is not entirely gender-specific, still there is a gender difference in the perception of traumatic experiences and their reporting.*

Keywords: *Adolescents, Gender differences, Hardiness, Parental Conflict, Stress.*

I. INTRODUCTION

Childhood is an important stage of development that determines the emotional, cognitive, and social background of a person during the further life.

Childhood experiences in the family set up are crucial in shaping the personality and the interaction between self and other parties in adulthood. Childhood trauma (abuse, neglect, loss, or exposure to dysfunctional family dynamics) can also be listed among the most important negative experiences at this stage. These traumatic experiences may interfere with the feeling of safety, attachment, and emotional security of a child, and this may affect their relationships and perceptions in future life. The manner in which people are processing and internalizing such early adversities might have an enormous influence on their relational patterns, emotional control, and trust of others. Even though childhood trauma is usually associated with the problems in adult relationships, not all people show the same reactions to them. Others could be intimacy challenged, communicational challenged or trust challenged whereas others could develop adaptive coping skills which will enable them to build healthy and meaningful relationships. Emotional resilience is one of the most important psychological factors that predetermine these consequences since it can be defined as the ability to react positively to adversity. This characteristic is described as the ability to control emotions, self-awareness, and the ability to overcome disturbing situations.

Professionally, it is also true that the more resilient adults tend to make the past traumatic experiences constructively than defining it in a negative way and make the relationships be defined by them. Therefore, resilience would act as a buffer in the long-term consequences of childhood trauma on the relational functioning in adulthood. Besides, the genders differences are also possible in the way people manifest, retaliate, and convey the effect of early trauma in their relationships. Men and women can vary in the expression of emotions, styles of attachment and coping. In order to comprehend the dynamics of adult relationships based on initial negative experiences, it is necessary to investigate the importance of gender variations in perceived childhood trauma and resilience, and investigate the connection between the two variables.

A. Significance

The current study is important because the trauma experiences of early childhood have a powerful impact on psychological development and the emotional functioning at adulthood that is a critical stage of relational adaptation. In order to facilitate healthy relationships, the understanding of the perceptions and reactions of adults towards the intimacy and conflict in relationships is critical as it is one of the main impacts of early life stress. The study assists in the explanation of how traumatic childhood environment affects the emotional and personality outcomes of the adult under the consideration of close relationships. The significance of this study is also that resilience is viewed as the positive attribute of psychological orientation, and the research does not always revolve around the negative aspects of anxiety or depression. Adaptability, emotional regulation, self-awareness and stress coping capability are indicators of resilience. The topic about the connection between childhood trauma and resilience helps to comprehend how the adverse experience that one had in his/her childhood may influence the adaptive coping pattern in adulthood. Besides, the study is also helpful in the perception of individual difference in relation to trauma and functioning of relationships. Understanding differences in these aspects among adults allows therapists, counsellors and other mental professionals to design trauma-informed interventions and support systems.

All in all, the results of the current paper can inform families, practitioners in practice, and psychologists to devise strategies that would assist adults to foster more healthy relationships and more secure attachment patterns in instances whereby past trauma still plays a significant role in relationships to the present day on a large scale

B. Objectives

- 1) To examine relationship.
- 2) To explore the impact of childhood trauma on relationships
- 3) To assess the correlation between childhood trauma and emotional well-being.

C. Rationale

Childhood experiences are core elements in the development of emotional development, attachment patterns, and interpersonal functioning in the lifespan of the individuals. Childhood trauma, which can be described as an exposure to negative experience during developmental years (Felitti et al., 1998), has been broadly identified as a high-risk factor in adverse psychological and relational problems in later life. Childhood stress may interfere with the feeling of security, trust, and emotional security of a child, which is essential to develop and build healthy relationships at the adult stage. The studies have indicated that people with childhood trauma histories are at high risk of having insecure attachment, problems with emotional regulation, and inability to form intimacy and trust (Bowlby, 1969; Mikulincer and Shaver, 2007). Adult relationships, such as romantic relationships and close friends, hinge on adequate communication, emotional sensitivity, and the ability to build intimacy and trust. Nevertheless, unresolved childhood trauma can result in coping styles that are maladaptive, phobia of abandonment, increased responsiveness to rejection and relationship insecurity (Herman, 1992). Research proves that grown ups with childhood misfortunes frequently complain of reduced relationship fulfilment, augmented quarrel and inability to uphold enduring commitments (Whisman, 2006). These trends point to the long-term effects of childhood negative experiences on adulthood relationship outcome. Whereas the available literature has explored the relationship between childhood trauma and certain variables of relationship e.g. attachment, or marital satisfaction, a limited number of studies have explored comprehensively childhood trauma as a predictor of general adult relationship quality. Thus, the purpose of this study will be to explore how childhood trauma can influence relationships in adulthood in terms of attachment patterns, emotional regulation and relationship satisfaction. The awareness of this relationship can be used to guide therapeutic interventions, trauma-informed counselling services, and prevention measures to promote healthier functioning of relationships. The results will be a good enlightenment to mental health practitioners, teachers, and policymakers in assisting people who went through negative experiences at a tender age.

II. REVIEW OF LITERATURE

Childhood trauma, which is an exposure to unpleasant events that include physical, emotional, or sexual abuse, neglect, or dysfunction in the home during childhood (Felitti et al., 1998) has been well noted as a powerful predictor of psychological and interpersonal problems in the long run. Traumatic experiences at a young age may come in the way of a child in terms of their sense of safety, trust and emotional security that are essential to normal development. During the process of becoming an adult, the unresolved trauma can affect how a person sees him or herself and others, especially in intimate and close relationships. As a result, the effect of childhood trauma on the relationships of adults has gained significance as a field of psychological investigation.

Attachment Pattern and Childhood Trauma. Attachment theory is one of the main theories that are applied to describe the effects of childhood trauma on relations in adulthood. Bowlby (1969) says that the experiences that children have in their early interactions with their caregivers influence the development of internal working models of self and other persons. Children can come to have insecure attachment styles when they are traumatized particularly in relationships involving care giving. According to the study conducted by Ainsworth et al. (1978), anxious and avoidant attachment patterns have been noted with references to the problematic relationships between adults in romantic relationships. Research has shown that victims of abuse or neglect during childhood develop anxious attachment with fear of abandonment and overly requiring reassurance or avoidant attachment with emotional detachment and feeling uncomfortable in close relationships. Mikulincer and Shaver (2007) observed that insecure attachment styles during adulthood are usually a result of the traumatic events that occur in early years and are characterised by the reduced relationship satisfaction and increased relationship conflict. Childhood trauma therefore has the ability to define relational anticipations and actions that remain lifelong. Emotional Control and Interpersonalization. Childhood trauma also influences emotional control, which is an important attribute to a healthy adult relationship. Suffering traumatic experiences may affect a child in such a way that they cannot recognize, feel, and cope with feelings. In a study, Cloitre et al. (2005) have found out that people who have experienced childhood trauma have a problem with increased emotional responsiveness and the inability to relax themselves in the stress of interpersonal interaction. Such issues in emotional regulation can be reflected in adult relationships through common misunderstandings, heated arguments, or withdrawal in the conflict. A person can perceive neutral events as threatening or react unrealistically to small disputes. Moreover, survivors of the traumatic events might develop a problem of trust and hypervigilance where they expect rejection or betrayal at all times. This trend may affect the relationships negatively and give rise to a chain of instability and discontent. Intimacy and Trust and Relationship Satisfaction. The aspect of trust and intimacy is essential elements of fulfilling relationships in adulthood. Nevertheless, trauma experienced in childhood, especially abuse committed by a care taker or a close family member may have a serious negative effect on the capacity of an individual to trust others. This problem is reported by victims of crimes as the study by DiLillo (2001) has shown that survivors of childhood sexual abuse share problems with intimacy and vulnerability in adult romantic relationships. Moreover, research findings have revealed that participants who had traumatic experiences in childhood have greater chances of having low levels of satisfaction in relationships. Whisman (2006) established that pre-marriage exposure to trauma was a factor that resulted in higher divorce and likelihood of experiencing marital distress. This could be attributed to maladaptive beliefs on oneself and anticipation of rejection which can break down intimacy and companionship. Survivors of traumas can either prevent emotionally close relations in order to prevent possible damage or be too clingy on a partner wanting to feel valued and safe. Conflict, Aggression and Revictimization. Childhood trauma also influences the relationships of adults in terms of conflict and aggression. Childhood exposure to violence may sensitize violent tendencies and heighten the chances of violent relations in adulthood. Widom, Czaja, and Dutton (2008) found that, the subjects who had been abused in childhood were more likely to become perpetrators and victims of intimate partner violence. More so, studies indicate that survivors of traumas can be more susceptible to revictimization. Because of disrupted boundaries, low self productive, and incapability to identify unhealthy relationships, those who have experienced childhood trauma can join or stay in abusive relationships. This keeps a circle of early trauma affecting later relational consequences that further reinforce negative patterns as the years pass. Mental Health as a Mediating Process. The relationship between childhood trauma and relationship problems in the adult years is usually mediated by mental health problems. Depression, anxiety, post-traumatic stress disorder (PTSD) and personality disorders have been associated with childhood trauma (Anda et al., 2006). The conditions may disrupt the relationship communication, emotional availability and conflict resolution. An example is that depression symptoms can cause a person to be withdrawn and less responsive to the needs of the partner and anxiety can cause one to be clingy or to demand insecurity. The PTSD symptoms including flashback or the feeling of emotional numbness may pose obstacles to intimacy and understanding. Therefore, psychological distress can lead to poor relationships since it can be untreated and minimally impact the overall relationship quality. Shielding Factors and Resilience. Although there is a close correlation between childhood trauma and relationship problems, not every person who has traumatic backgrounds has adverse relationship consequences. Adulthood factors which create resilience include protective factors like social support, therapy and secure relationships. According to the research conducted by Rutter (2012), later maladaptive patterns can be altered by positive interpersonal experiences later in life. Trauma-informed care and attachment-based therapy interventions have demonstrated potential in enhancing relationship functioning. They can redefine their relational patterns by engaging in emotional awareness, communication skills and healthy coping techniques which can be gradually developed. These results reveal that although childhood trauma has great dangers, it is not determined by it. Conclusion The reviewed literature shows that there is a strong correlation between relationship functioning in the adult and childhood trauma. Negative experiences in the early years affect the attachment style, emotional regulation, trust, intimacy, and

conflict styles, which tend to lower satisfaction in relationships and raise relationship instability. This association is also mediated by mental health problems, which exacerbate interpersonal problems. Nonetheless, these effects are avoidable by the application of resilience factors and therapeutic interventions that would allow the development of healthier adult relationships. Further studies on the concluding mechanisms of childhood trauma to relational outcomes and effective tactics to help trauma victims develop secure and rewarding relationships should be pursued in future.

III. RESEARCH GAP

Despite the fact that quite a good portion of the literature has been developed to explore the effect of childhood trauma on adult relationships, the current body of literature has been largely devoted to illuminating on negative psychological consequences like attachment insecurity, trust, emotional, and interpersonal conflicts. Most studies can emphasize maladaptive tendencies such as avoidance, dependency, or relationship instability, and the research has a relative focus on less attention on learning positive changes or development that could arise in spite of the early negative experiences. In particular, the contribution made by resilience-focused personality factors, including emotional resilience, post-traumatic growth, and adaptive coping is under-studied in terms of the development of healthy adult relationships. Although it is accepted that not all people with prior experiences of childhood traumas cannot have a stable and happy relationship, little empirical studies investigate how this adaptive qualities come to be and how they operate in intimate or social relationships. This leaves a gap in the knowledge about the possibility and the process of how early traumatic experiences can lead to the emergence of strength-based relational outcomes in adulthood. Furthermore, the extant literature tends to use childhood trauma as a direct risk factor of dysfunctional patterns of relationships in a manner that does not adequately explore the mediating and moderating variables that mediate the relationship. Other factors including coping styles, social support, emotional intelligence and individual differences are not always incorporated in the existing models. This has resulted in a lack of clarity on how such people succumb or overpower the adverse consequences of trauma in their adult relational lives. Also, most studies have been carried on the background of the Western culture thus raising questions on the generalization of the results to different groups of people. Family-related cultural differences in family relationships, emotion expression, expectations of relationships and coping styles are important but poorly represented in literature. It is a weakness of cross-cultural studies because the study cannot be applied to a non-Western society due to the lack of cross-cultural research. Hence, this is why a study investigating the connection between childhood trauma and adult relationships both in terms of risk and resilience and including the gender-based comparisons and multiethnic populations is necessary. Filling such gaps can help in a more comprehensive and balanced insight in to the effect of early negative experiences on relational functioning in adulthood.

IV. KEY FINDINGS

The important discoveries of the research assisted in the perception of the connection between childhood trauma and the patterns that are noticed in adult relationships. Having different facets of early trauma including emotional neglect, physical abuse, inconsistent caregiving, and being exposed to family conflict showed that they had serious correlations with relational functioning in the future. The mean differences showed the negative means indicates that those exposed to childhood trauma complained of more troubles in trust and emotional intimacy, and communication than those exposed to lower levels of trauma, which means that actions and perceptions in relationships among adults are influenced by early adverse exposure. Such differences show that childhood family experiences have a strong impact on attachment styles and relational expectations when people grow up. But, there was nothing notable in the yearning of being in close relationships, indicating that even after the traumatic experiences, people still want to connect with and have emotional attachments. The other significant result was moderately positive significant relationships between childhood trauma and maladaptive relationships pattern including avoidance, dependency, or fear of abandonment. The result shows that the more individuals are exposed to trauma, the more the issues of relationship become difficult. Meanwhile, others were found to have adaptive coping styles which typify resilience and formation of stable relationships despite early adversity. Altogether, the results confirm the assumption that childhood traumatization has a notable impact on the nature of relationships in adulthood, specifically, emotional management and trust between people, though the ability to build meaningful relationships is not entirely depleted.

V. FUTURE IMPLICATIONS

In future research, the mechanism by which childhood exposure to trauma shapes the trend of adult relationships should also be investigated because current evidence shows an excellent correlation between childhood negative experiences and adult relationship problems.

Future studies ought to determine the possible moderating and mediating factors that could influence this relationship including attachment styles, emotional regulation, and self-concept and investigate whether individual personality factors have a role to play in the perception and processing of trauma in the long-term. The manner in which one is guided through adult relationships because of childhood trauma could be determined by a number of factors, such as the social support, coping, exposure to therapy, cultural orientation and family dynamics later in life. These variables could be taken to give a more detailed picture of the development of resilience or vulnerability in relationships. It is also significant that future research should investigate differences in gender-specific approaches to emotional processing and coping since men and women can have different results in terms of internalizing and communicating the effects of the trauma on intimate relationships. Moreover, to investigate the lived experiences more thoroughly, it might be important to include the qualitative methodology to learn how people perceive and cope with the permanent impact of trauma in everyday interrelations. Lastly, the build of specific counselling and intervention programs and their implementation can be the subject of future studies. These interventions can be applied both in the clinical and community context and can be focused on improving emotional awareness, secure attachment, and adaptive coping and thereby, healthier and more stable relationships between individuals with childhood trauma.

VI. CONCLUSION

The present study was carried to examine how childhood trauma affects adult relationships and to analyse the connection between abused childhood experiences and the subsequent interpersonal functioning. The findings are applied to understand how childhood experiences influence the patterns of their emotions as well as attachment styles and relationship dynamics in adulthood. The paper offers a balanced view of adult relationships, in both risk factors (childhood trauma) and the positive outcome (coping and resilience). The results depicted that those who had encountered greater levels of childhood trauma had observable variations in their adult relationship pattern that included problems of trust, emotional bonding, communication and conflict management. These findings can be used to indicate that early traumatic events are important factors that shape how adults perceive and practice romantic and interpersonal relationships. Nevertheless, it was also found that differences existed depending on personal coping styles, support networks and personal development, which means that not every person reacts alike to the trauma. Interestingly, although childhood trauma is mostly linked with poor relationship outcomes, the study also revealed that there are other persons who gain adaptive coping mechanisms and emotional resilience with time. In other scenarios exposure to adversity was associated with heightened self-knowledge, compassion and relationship strength. This shows that as much as childhood trauma may be a risk factor, it may also serve to bring about psychological strength in other people. All in all, the research highlights the significance of being vulnerable and resilient regarding the relationships in adulthood. The study is important in illuminating how childhood trauma can be effectively mitigated over time and the likelihood of adaptive adaptation to the stressor in future educating towards healthier relations patterns and emotional states as an adult.
