[7]*Project Guide, Department of Computer Science and Engineering, Bonam Venkata Chalamayya Engineering College, Affiliated to JNTU Kakinada, Andhra Pradesh-533210, India*

Abstract: ***A web-based program called Life Link: An Online Blood Donation Platform was created to close the gap between blood donors and receivers by offering a quick, dependable, and effective digital alternative. The system's main goals are to streamline the blood donation procedure, minimize delays during crises, and guarantee that people in need may get blood on time. Users can manage profiles, register as donors or recipients, and search for blood by location and blood group on the portal. While administrators supervise user behavior and system functions, blood banks are able to update and track blood supply levels in real time. Sensitive data can only be accessed by authorized persons thanks to secure authentication. Additionally, the system notifies and alerts donors when there is an urgent need for blood, improving responsiveness in dire circumstances. With a user- friendly interface and responsive design to guarantee accessibility across devices, Life Link was created utilizing contemporary web technology. The technology decreases manual labor, lowers errors, and improves transparency by automating blood request processing, donor management, and stock monitoring. All things considered, Life Link helps save lives by utilizing technology to establish a centralized, effective, and reliable blood donation environment.***

Index Terms: ***Web app for blood donation, donor management, blood bank system, Django framework, and healthcare technology***

I. INTRODUCTION

Since blood is required to treat patients in emergencies, surgeries, accidents, and chronic illnesses, blood donation is an essential component of contemporary healthcare sys- tems. Due to poor coordination between donors, blood banks, and patients, blood shortages persist in many locations despite advancements in medical technology. Delays in finding suit- able donors or blood units can have serious consequences in emergency situations, including fatalities.

Manual procedures, in-person trips to blood banks, and constrained communication channels are the mainstays of tra- ditional blood donation systems. These methods frequently lead to poor donor engagement, delayed responses, and a lack of real-time blood flow information. To enhance donor-recipient matching and inventory management, a number of studies have suggested online blood donation and blood bank administration systems. Even though these systems have demonstrated im- provements in efficiency and accessibility, many of the current solutions don't offer a fully integrated platform and instead concentrate on specific functions like donor registration or blood stock management.

This article presents Life Link, a web-based blood donation platform that unifies patients, blood banks, and blood donors into a single, centralized system to address these problems. The suggested infrastructure provides secure user identification, automated request processing, real-time inventory management by blood banks, and real-time blood search based on location and blood group. Life Link aims to increase the overall effectiveness of the blood donation process, encourage transparency, and reduce reaction times during emergencies by utilizing contemporary digital technologies.

II. LITERATURE REVIEW

Numerous investigations have been carried out to enhance blood donation systems' effectiveness and accessibility using digital platforms. Abdul-Gafaru et al. introduced an online blood donation system that uses a centralized web-based platform to cut down on donor-recipient matching delays. In comparison to conventional manual procedures, their system, which concentrated on donor registration, blood stock management, and administrative control, demonstrated increased efficiency. Nevertheless, the implementation did not completely incorporate real-time emergency alarm mechanisms and instead focused on inventory management.

©IJRASET: All Rights are Reserved

A blood bank administration system that uses a browser- based application to keep track of donor information, blood group availability, and recipient requests was proposed by Priyanka Halle et al. The method decreased manual labor in blood banks and increased transparency. Despite its advantages, the method lacked sophisticated automation capabilities like integrated donor responsiveness and real-time notifications, and it depended on little user engagement.

A blood donation and management system that prioritized donor engagement, appointment scheduling, and safe data pro- cessing using contemporary online technologies was presented by Kabilan et al. While maintaining data privacy, the method improved communication between healthcare practitioners and donors. However, the technology did not adequately solve direct patient-to-donor contact during emergencies because its primary focus was on institutional utilization.

A web-based blood donation management system was cre- ated by Selvin Jerald et al. to automate the processing of blood requests and the preservation of donor data. In finding donors, the system decreased reaction times and increased search efficiency. However, issues including disjointed system design and poor real-time coordination between patients, blood banks, and donors persisted.

Although contemporary systems have greatly improved blood donation management, it is clear from the review of the literature that most solutions only handle particular aspects of the procedure. A comprehensive, real-time, integrated web- based network that links patients, blood banks, and donors inside a single system is required. By offering a centralized and responsive blood donation environment, the proposed Life Link technology seeks to overcome these constraints.

III. PROPOSED SYSTEM

A. *System Overview*

The goal of the web-based blood donation platform Life Link is to establish a cohesive ecosystem that links patients, blood banks, and donors. The system is intended to streamline blood donation procedures, enhance stakeholder communica- tion, and guarantee prompt access to blood in an emergency. The platform lessens reliance on human coordination by digi- tizing and automating critical processes.

B. *User Roles and Responsibilities*

The proposed system has four primary user roles. Donors can register on the portal by providing their personal informa- tion, blood type, and availability status. Patients or recipients can submit blood requests by providing the required blood group and location. Blood banks manage blood inventories by updating stock availability and monitoring blood units in real time. An administrator is responsible for overseeing system operations, managing users, and ensuring data consistency.

C. *Functional Workflow*

The system finds compatible donors and local blood banks when a patient submits a blood request. When there is an urgent need, eligible donors receive notifications, allowing for a quicker response. Blood banks ensure accurate real-time data availability by updating inventory status following successful donations.

D. *Security and Reliability*

The system includes secure authentication and authorization procedures to safeguard private and sensitive medical data. Cer- tain functionalities are only accessible by authorized users ac- cording to their roles. Controlled access and organized database management preserve data dependability and integrity.

E. *Advantages of the Proposed System*

The suggested Life Link platform minimizes errors fre- quently found in conventional blood donation systems, im- proves transparency, and speeds up response times. The system enhances donor engagement, facilitates effective blood distri- bution, and helps save lives by providing an integrated and user-friendly interface.

IV. SYSTEM ARCHITECTURE

The web-based client-server architecture used in the creation of the Life Link platform guarantees accessibility, dependabil- ity, and simplicity. Through a centralized system, the architec- ture emphasizes smooth communication between blood banks, patients, and donors. By facilitating digital communication and real-time data access, it does away with the need for manual coordination.

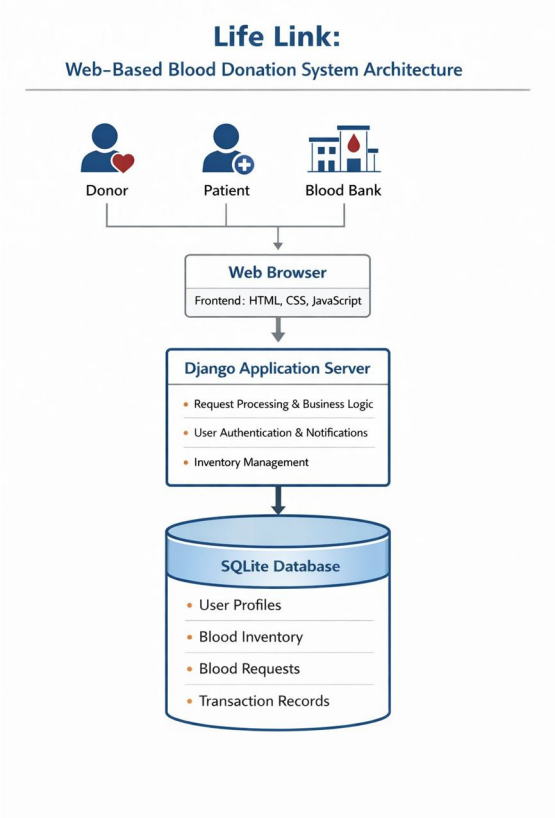

Fig. 1. System Architecture of the Life Link Platform

The user interface layer, the application layer, and the database layer are the three primary parts of the system architecture. The system is accessed via a web browser by users, including blood bank employees, patients, and donors. Users can register, log in, search for blood, submit requests, and update blood availability using the frontend's responsive and user-friendly interface, which is created using HTML, CSS, and JavaScript.

The Django application server is the main part of the system. It handles all requests from the frontend. The application layer takes care of things like user authentication, processing blood requests, matching donors, and updating the blood inventory.

Django keeps role-based access control in place while making sure that users can safely talk to the database. The server processes the request and finds suitable donors or blood banks based on the patient's blood type and location when they ask for blood.

An SQLite database is used by the data layer to store and manage system information, such as user profiles, blood inventory details, and blood request records. Django's Object Relational Mapping (ORM) is what you use to talk to the database. This makes sure that the data stays the same and lowers the chance of mistakes. The centralized database lets people and blood banks see correct and current information in real time.

This architecture makes it easier for data to move around, speeds up response times in emergencies, and makes sure the system can grow. The architecture makes it easy to add new features like notification services or deploy the system on cloud platforms in the future without having to make big changes to the current system.

Bank inventory, and blood request records, are stored in the database. The database is accessed through Django's Object Relational Mapping (ORM), which makes structured data management possible and simplifies the process of creating raw SQL queries. Data consistency and effective information retrieval are guaranteed by this method.

V. IMPLEMENTATION

This part talks about how to use the Life Link blood donation platform in real life. The system is a web-based app with a clear separation between the front end, back end, and database parts. The implementation is all about making blood donation activities easy, safe, and quick.

ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538
Volume 14 Issue III Mar 2026- Available at www.ijraset.com

A. Frontend Implementation

JavaScript, HTML, and CSS are used in the development of the Life Link platform's front end. Web pages like user registra- tion, login, blood search, and request forms are designed using HTML. CSS is used to improve the application's visual appeal and guarantee a responsive layout that works on a variety of devices. Client-side interactions, input validation, and dynamic updates are handled by JavaScript without the need for frequent page reloads. Donors, patients, and blood banks can interact with the system with ease thanks to the frontend's user-friendly interface.

B. Backend Implementation

The Django framework in Python is used to implement the system's backend. The application's core business logic, such as inventory management, role-based access control, blood request processing, and user authentication, is handled by Django. Django views are in charge of processing data, responding appropriately, and receiving requests from the frontend. Additionally, the framework offers integrated security features like form validation and defense against unwanted access. The system maintains scalability and maintainability while guaranteeing dependable communication between the database and user interface thanks to the use of Django.

C. Database Implementation

The database used by the system to store application data is SQLite. Because of its ease of use and suitability for academic and prototype-level applications, SQLite was selected. Important data, including user profiles, donor information, blood

Fig. 2. Technology Stack Used in the Life Link Platform

D. Development Tools and Technologies

The Life Link platform is implemented using a variety of technologies and development tools. HTML, CSS, and JavaScript are used for frontend development, while Python and the Django framework are used for backend processing. The database management system is SQLite. Code editors like Visual Studio Code and common web browsers are used for development and testing. In order to ensure correct formatting and adherence to IEEE standards, Overleaf is used to prepare the IEEE research paper using LaTeX.

VI. PROJECT FLOW AND SYSTEM WORKING

This section describes how various users interact with the Life Link platform and explains how it operates. Through an organized, role-based workflow, the platform is intended to facilitate seamless coordination between donors, patients, and blood banks. Through a secure login, each user gains access to the system and carries out particular tasks according to their role.

A. Donor Workflow

The donor module is meant to make the process of giving blood easy and well-organized. A donor first signs up for Life Link and then logs in using their real credentials. Once the donor logs in successfully, they can see and change their personal profile information, like their blood type, contact information, and availability status.

©IJRASET: All Rights are Reserved

People who want to give blood can choose a date and time that works for them. When a patient asks for blood or a blood bank finds a need for blood, the system checks to see if the donor is eligible based on their blood type and location. People who can donate are told about the requirement, which lets them respond quickly. This structured workflow makes sure that donors are used efficiently and only contacted when their blood type is needed, which cuts down on unnecessary communication and delays.

B. Patient Workflow

The patient module's main goal is to make it easy and quick to get blood in emergencies. Patients sign up for and log in to the Life Link platform to ask for blood. Once they log in, patients can look for the blood groups they need based on where they are and whether they are available. The search results show blood banks and possible donors that meet the criteria you set.

After a request is made, the system processes it and sends it to the relevant blood banks and qualified donors. The status of their requests, such as pending, approved, or fulfilled, can be monitored by patients. Patients can receive timely assistance without the need for in-person visits or phone calls thanks to this workflow, which reduces manual labor.

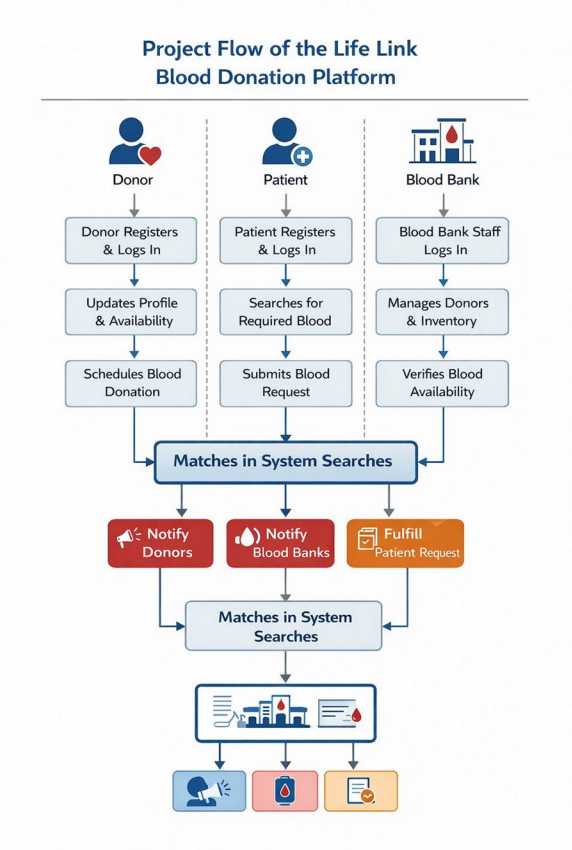

Fig. 3. Flowchart of the Life Link Platform

C. Blood Bank Workflow

In order to maintain appropriate inventory control and man- age blood availability, the blood bank module is essential. Employees at blood banks use their authorized login credentials to access the system. They can view incoming blood requests, manage donor information, and update blood inventory details following authentication.

Blood banks update stock levels following donations or transfusions and keep track of available blood units for various blood groups. The blood bank checks for availability when a request for blood is received and reacts appropriately. The sys- tem guarantees transparency and avoids discrepancies between requested and available blood units by keeping up-to-date inventory data. This process increases operational effectiveness and facilitates better emergency decision-making.

All things considered, a smooth blood donation procedure is guaranteed by the coordinated communication between donors, patients, and blood banks via the Life Link platform. The system offers a dependable digital solution for efficient blood donation management, speeds up response times, and improves communication.

VII. RESULTS AND DISCUSSION

The Life Link blood donation platform was effectively devel- oped and put into use as a web-based system that links blood banks, patients, and donors. The system's efficacy, usability, and dependability were assessed through testing under various user scenarios. The findings show that the platform effectively facilitates blood donation management and enhances stake- holder coordination.

Donors were able to successfully register, log in, update their availability, and schedule blood donations during testing. The system produced the proper alerts in an emergency and correctly matched donor blood groups with patient needs. Compared to conventional manual methods, this shortened the time needed to find suitable donors.

Patients could use the platform to find the blood groups they needed based on where they lived and send blood requests. The system handled these requests correctly and showed the most up-to-date information about their status. This made things clearer and let patients keep track of their requests without having to call or email someone else.

The system helped blood banks keep track of donor infor- mation and blood supplies. Real-time updates to the inventory made sure that the blood stock was always visible. By syn- chronizing updates across the platform, the system effectively stopped inconsistencies in blood availability data.

In general, the results show that the Life Link platform makes it easier to donate blood, cuts down on the time it takes to respond to emergencies, and makes blood donation services more efficient. The system is a reliable and scalable solution that can be expanded to support more users and new features.

Fig. 4. Result Output of the Life Link Blood Donation Platform

VIII. CONCLUSION

The web-based blood donation platform Life Link, which links donors, patients, and blood banks via a single, centralised system, was introduced in this paper. By facilitating online registration, blood search, request processing, and inventory management, the suggested platform streamlines the blood donation procedure. The system lessens manual labour and enhances stakeholder coordination by automating these tasks. The deployment of Life Link shows how web-based so- lutions can greatly increase the effectiveness and openness of blood donation services. The system facilitates quicker emergency response, increases donor participation, and offers timely access to blood information. All things considered, the platform offers a useful and dependable way to oversee blood donation operations and may even help save lives. Mobile applications, real-time notification services, and so- phisticated security features can be added to the system in the future. Scalability and performance can be further enhanced by extra features like cloud-based deployment and location-based donor matching. A larger user base may benefit from the Life Link platform thanks to these improvements.
