I. INTRODUCTION

Chromatography is a powerful analytical technique widely used for the separation, identification, and quantification of components in complex mixtures. It was first developed by Russian botanist Mikhail Tsvet in the early 20th century as a method for separating plant pigments, but it has since evolved into a cornerstone technique in numerous scientific disciplines, including chemistry, biochemistry, environmental science, and clinical diagnostics. The term "chromatography" derives from the Greek words chroma (color) and grapho (to write), initially referring to its use in separating colored compounds, though the method now extends to a vast range of analytes, many of which are colorless (1).

Chromatography works on the principle of differential partitioning between a stationary phase and a mobile phase. The sample mixture is introduced to a column or surface, where it interacts with the stationary phase. The mobile phase, typically a liquid or gas, moves the components through the system, with different substances in the mixture migrating at different rates depending on their chemical properties (such as polarity, size, or affinity for the stationary phase). This differential movement leads to the separation of the components as they travel through the chromatographic system (2).

The primary types of chromatography include:

1) *Gas Chromatography (GC):* Utilizes a gaseous mobile phase and is typically used for the separation of volatile organic compounds. GC is commonly employed in environmental analysis, forensic science, and the pharmaceutical industry for purity testing (3).
2) *Liquid Chromatography (LC):* Involves a liquid mobile phase and is versatile for separating a broad range of substances, including drugs, peptides, and nucleic acids. High-performance liquid chromatography (HPLC), a subtype of LC, is known for its high resolution and is widely applied in both research and clinical settings for drug analysis and environmental monitoring (4).
3) *Ion-Exchange Chromatography (IEC):* This method is based on the exchange of ions between the stationary phase and the mobile phase. IEC is often used for the separation of charged molecules, such as proteins, nucleic acids, and small ions (5).

4) *Affinity Chromatography:* Based on specific interactions between a target molecule (such as an enzyme, antibody, or receptor) and its ligand attached to the stationary phase. This technique is highly selective and is commonly used in biochemistry and biotechnology for protein purification (6).
5) *Size upgrade Chromatography:* Recent advances in chromatography have focused on increasing separation efficiency, speed, and sensitivity. Additionally, chromatography has become an integral part of two-dimensional chromatography, which combines multiple separation mechanisms to handle more complex mixtures, such as in proteomics and metabolomics research.

The growing demand for green and sustainable methods in scientific analysis has led to the emergence of green chromatography, which emphasizes the reduction of harmful solvents and minimizes waste production. Such advancements not only improve environmental sustainability but also align with modern trends in sustainable analytical chemistry (7).

II. PRINCIPLES OF CHROMATOGRAPHY

This interaction is influenced by the size, polarity, and charge of the components, leading to the successful separation of mixtures. Through this mechanism, chromatography serves as a critical tool for purifying compounds and analyzing complex mixtures in diverse scientific fields (8,9).

A. *Types of Chromatography*

Chromatography techniques can be categorized in several ways, including by the type of stationary phase used, the method of separation and the types of instruments involved. Below are some of the most common chromatography methods:

1) *Gas Chromatography (GC):* Gas chromatography is used for separating and analyzing volatile compounds. The stationary phase is typically a solid or liquid coating inside a column, and the mobile phase is an inert gas like helium or nitrogen (10). GC is widely used in environmental science for pollutant detection and in the petrochemical industry (11).
2) *Liquid Chromatography (LC):* like drugs, peptides, and organic compounds (12). HPLC and UHPLC are especially useful in pharmaceutical analysis for ensuring drug purity and quality control (13).
3) *Thin-Layer Chromatography (TLC):* TLC is commonly used for qualitative analysis and rapid screening of samples in the food, pharmaceutical, and forensic industries (14).
4) *Paper Chromatography:* It is widely used in educational settings and for basic research (15).
5) *Ion-Exchange Chromatography:*It is widely used for purifying proteins, nucleic acids, and separating metal ions (16). This technique plays a critical role in the biotechnology and pharmaceutical industries (17).
6) *Size Exclusion Chromatography (SEC):* This technique is particularly useful for analyzing polymers and proteins (18).
7) *Affinity Chromatography:* Affinity chromatography is based on the specific interactions between the stationary phase (often functionalized with a ligand) and the target molecule.
