# A Comparative Study on Large Language Models in Text-to-Image Generation: Applications, Characteristics, and Future Prospects

Saurav, Dr. Naveen Kumar Amity University Patna

Abstract: Text-to-image era, driven by later propels in huge dialect models (LLMs), has quickly advanced from simple pixel blend to the era of high-resolution, relevantly exact pictures from characteristic dialect prompts. This paper presents a comprehensive survey of the basic standards, engineering components, applications, and experimental comes about related to LLM-driven text-to-image frameworks. We look at the integration of transformers with generative ill-disposed systems (GANs)[1], dissemination models[2], and multi-modal encoders such as CLIP (Contrastive Language Image Pretraining)[3], nearby more current systems like DALLE[6] and Midjourney. The consider too dives into the confinements, moral concerns, and versatility challenges inborn in these frameworks. An experimental test comparing the execution of distinctive models over incite sorts is displayed, highlighting their qualities and disappointment modes. The paper concludes with bits of knowledge into future patterns, counting real-time era, aesthetic imagination enlargement, and intuitively plan devices. A timeline of major breakthroughs is additionally included to follow the fields advancement.

Keywords: Big language models, text-to-image generation, artificial intelligence, diffusion models, generative adversarial networks, clip, dall•e, multimodal learning, image synthesis, prompt engineering.

# I. INTRODUCTION

Recent advancements in natural language processing (nlp) have discovered large language models (llms)[14] that can understand and generate human language that is natural, coherent, and rich in meaning[94]. Computer vision has experienced significant growth, particularly in the field of image synthesis[58]. Text-to-image synthesis merges the realms of natural language processing and computer vision, utilizing textual inputs to generate either realistic or stylized images. This essay explains how language models have revolutionized text-to-image generation and how the understanding of language and the ability to visualize images are interconnected. The primary goal of this research is to break down the components of architectural design, training methods, and practical applications of image generation systems based on llm. We analyze prominent industry players such as openai's dall•e, midjourney, stable diffusion, and imagen, which are currently considered the most advanced in the field of multimodal artificial intelligence. By examining the performance, limitations, and applications of this paper, it aims to serve as a valuable resource for academic research and practical applications.

# II. TEXT-TO-IMAGE GENERATION

Large language model (llm)-driven text-to-image synthesis is an advanced artificial intelligence (ai) process that converts written descriptions into visual images that are equivalent in meaning. The process starts with a user giving a prompt, such as "a cat sitting on a windowsill," which is then analyzed by the model. The llm transforms the prompt to comprehend the scene, objects, relationships, and implied style of the text. This semantic understanding is then typically transformed into an intermediate form, such as image embeddings. These embeddings are utilized as guidelines for a diffusion-based or a generative adversarial network (gan) model to generate the image. Several systems, including dall•e, imagen, and midjourney, utilize llms in conjunction with vision models to accomplish this. The vision model is designed to handle spatial and visual data, while the llm is specifically designed to handle linguistic richness. Researchers utilize extensive datasets of image-text pairs[61,86,87] to train models, aiming to identify connections between visual content and language[88]. As a result, they can create images that are both coherent and contextually appropriate, often resembling real-life scenes, even when inspired by abstract or imaginative ideas. Engineers strive to enhance the quality and specificity of output by fine-tuning and implementing prompt engineering techniques. These models have the ability to produce images in various formats, including cartoon, realistic, sketch, or surreal, depending on the given prompt.

# International Journal for Research in Applied Science & Engineering Technology (IJRASET) ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538 Volume 13 Issue V May 2025- Available at www.ijraset.com

Attention mechanisms assist the model in focusing on the relevant text components when creating images. The process may include steps like denoising in diffusion models to gradually construct visual features. Text-to-image generation has applications in various fields, including art, design, marketing, education, and entertainment. It's also beneficial for accessibility, as users can easily visualize the text material. Challenges exist, but they mainly come in the form of ethical concerns, bias in the training data, and misuse. Scientists are actively working on aligning the outputs generated by different generations with human values and safety regulations. User feedback is also a valuable method of improving reliability and relevance. As technology advances, the distinction between written and visual creativity becomes more indistinct. The combination of language and visual cues is shaping the future of how humans interact with computers.

#### A. Generative AI

Generative AI encompasses various artificial intelligence systems that generate content automatically, including text, images, music, and computer code. Traditional AI concentrates on tasks such as categorization and forecasting, while generative AI generates novel outcomes by merging vast amounts of data. The system utilizes advanced deep learning techniques, such as generative adversarial networks (gans), variational autoencoders (vaes), and transformer models, to achieve its objectives. The training process for these models entails examining vast amounts of data, enabling them to generate outputs that are both lifelike and contextually precise. Chatgpt is a text generator, whereas dall•e is specifically designed for image synthesis. Generative AI can produce stunning works of art by utilizing intricate neural network calculations when given specific text prompts. The different fields, including design education and scientific research, now view this technology as a valuable tool that enhances creativity and streamlines the creation process.

Generative AI technology generates molecular simulations for healthcare drug discovery, automates music composition, and animates scenes for entertainment purposes. The technology offers numerous benefits, but it also introduces new challenges regarding the spread of misinformation and the ethical use of creative work, as well as questions about ownership. Developers strive to establish protective measures and transparent processes, encouraging responsible behavior and establishing clear standards for the deployment of AI systems. The continuous progress of generative AI showcases its immense potential to transform creative and problem-solving capabilities, as well as enhance productivity across diverse industries.

# III. LITERATURE REVIEW

#### A. The History of Creating Images from Texts

The early attempts at text-to-image synthesis were constrained by low-resolution outputs and a lack of correlation between the text and images. The implementation of staged generation and attention mechanisms was accomplished through the utilization of stackgan and attngan. Regrettably, these systems were incapable of capturing the intricate details of prompts.

# B. The Function of CLIP and LLMs

For the first time, ai clip systems marked the introduction of new models. From that point, models were able to process both images and texts simultaneously. These systems allow for the utilization of powerful language models like GPT-3 or its successors, which require text analysis to generate guidance for images. When combined with dall•e, that integrated the gpt like decoder with vq-vae image tokenizer:s, a new record was set that pushed the boundaries of prompt fidelity and imagination.

# C. Emergence of Diffusion Models

Stable diffusion and imaged standardization were used to create modifications in diffused-based techniques for text to image generation. These models utilize guided textual embeddings to address noise in the iterative refinement process. Diffusion models are considered more effective than gans, which often experience mode collapse due to the lack of diversity in the generated outputs and their lack of realism.

#### D. The comparatives of contemporary models

## IV. RESEARCH DESIGN AND METHODOLOGY

#### A. Research Discussion

The introduction of llm has significantly influenced the range of images that can be generated from input text and images, particularly in terms of capturing the essence of meaning and imagery. Traditional models struggled to capture intricate descriptions or contextual connections between entities, but llms have improved this capability by developing a more comprehensive understanding of syntax, semantics, and intent within natural language prompts. These includes dallee, imagen and stable diffusion, which utilize or couple llms with language decoders, resulting in obtaining rich user intent preserving embeddings whose subtleties guide the image generation pipeling towards achieving greater coherence and semantic alignment with the intended user requests. These models have the ability to transform subtle details like adjectives, relational phrases, and abstract concepts into visual components, thanks to their representational capabilities. One of the most remarkable aspects of models like openai's dall-e 2 and google's text-to-image generators is their ability to generate highly accurate images from a diverse range of abstract and surreal prompts. There were models that struggled with imagination, but these models have no problems creating coherent and even enjoyable images, which is a significant advancement in overcoming the limitations of traditional generative models. The implementation of diffusion models, enabling iterative image refinement, is a significant advancement as images now exhibit greater coherence and improved quality. Furthermore, these models can incorporate supplementary data, such as user sketches or layout hints, enhancing their versatility and applicability. Despite this, some challenges persist. Numerous models struggle with tasks that demand accurate measurements of space, ratios, and the interaction between objects. The output of 'a cat sitting under a tree beside a red bicycle' would display cats and bicycles, but the spatial arrangement would be inaccurate. Additionally, most models struggle to create effective writing or advertisement banners within the images. Bias and ethical concerns arise due to society's preconceived notions and stereotypes, which are often reflected in images and content. These biases can be perpetuated by the models, as they are trained on data that may contain these biases. Despite their imperfections, the systems that combine images from text have significant potential applications in various fields, including creativity and tasks. In marketing and design, the systems streamline the creative process by facilitating quick prototyping of concepts like mood boards and advertisements. Artists and illustrators often collaborate with the systems, using them as sources of inspiration or as tools to create initial drafts. In the academic realm, these models enhance the learning experience by offering customized visual aids that align with the content of the lessons, making them more accessible and comprehensible. In the world of gaming and film, they are employed for conceptual and background art, as well as visualizing scenes. Fashion designers utilize text-to-image tools to assist in the creation of garments, either based on descriptions or predictions about current fashion trends. Medical researchers are investigating the potential of these systems to present medical reports or create synthetic images for training diagnostic models. Additionally, there are applications that assist the visually impaired by utilizing these systems to generate illustrations based on descriptions of written texts. In the near future, e-commerce platforms will have the capability to display real-time visual representations of products based on customer descriptions. To enhance user creativity and engagement, social media platforms are also utilizing artificial intelligence (ai) to automate image creation. Additionally, the widespread adoption of systems in the creative, industrial, and academic sectors underscore the significant influence these technologies can wield. As these models become more accurate, controllable, and fair, they will pave the way for increased utilization of text-image generation in an individual's communication and interaction with visual content. In summary, the implementation of llms in image generation systems enhanced semantic coherence, and machines' comprehension of language became more akin to human understanding, allowing a machine to visualize it. Although these models possess remarkable capabilities, spatial reasoning, accuracy, ethics, and other domains continue to present challenges.

#### B. Methodological Framework

This study combines a theoretical analysis and an empirical investigation. Information was gathered from scholarly articles, technical blogs, and research papers. The empirical tests entail creating images using predefined prompts and assessing them based on their realism, coherence, and creativity.

#### C. Data Collection and Prompt Curation

A collection of prompts aiming to assess different capabilities of language understanding were composed:

- Descriptive: "A lion sitting on a throne made of clouds."
- Abstract: "The concept of time visualized as a melting clock in a neo desert."
- Instructional: "Design a logo for a futuristic space travel company."

ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538 Volume 13 Issue V May 2025- Available at www.ijraset.com

# V. TIMELINE OF DEVELOPMENTS

- Year Milestone
- 2015 Source of gans by goodfellow et al.
- 2017 Transformers were introduced in nlp. (vaswani et al.).
- 2018 StackGAN and AttGAN were an early benchmark.
- 2020 Clip and vq-vae improve multimodal representations[17,68].
- 2021 Dalle, glide and ldm architectures were implemented Introduced[13].
- 2022 Imagen and midjourney establish new benchmarks for image Quality[63]
- 2023 Une diffusion régulière rend les modèles de diffusion répandus.
- 2024 Generating Content on the Go, Immediately.

# VI. APPLICATIONS OF LLM-BASED TEXT-TO-IMAGE SYSTEMS

- 1) Content Creation and Design: Creators and designers utilize tools like midjourney to generate concept art, mood boards, and visual assets for various purposes, including advertising, game development, and film production.
- 2) Education and Research: Teachers employ AI-generated visual aids to illustrate objects. Scientists utilize generated data for simulations or modeling of rare occurrences.
- 3) Healthcare and Medical Imaging: In the early stages of development, models are assessed for their potential use in generating anatomical drawings or enhancing training data for rare medical conditions.
- 4) E-commerce and Marketing: Text descriptions can be transformed into visual representations, enabling dynamic ad creation, prototyping, and personalized experiences for customers.
- 5) Accessibility and Assistive Technology: Individuals with visual impairments are assisted by text-to-image systems that convert text into visual representations or provide auditory descriptions of visual content.

# VII. LIMITATIONS AND ETHICAL CONSIDERATIONS

- 1) Bias in Training Data: LMs are often trained on datasets that contain social and cultural biases[27,28,36,39], which can be reflected in the images they generate[38].
- 2) Intellectual Property Issues: Due to the fact that these models are trained using scraped web images[41], concerns regarding copyright infringement, plagiarism[40], and proper attribution come into play.

ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538 Volume 13 Issue V May 2025- Available at www.ijraset.com

- *3)* Abuse and Deepfakes: Advanced power technology can be utilized for spreading false information, creating deepfake videos, or generating explicit content.
- 4) Environmental Impact: The process of training and running large models requires a significant amount of computational power[34], which in turn contributes to carbon emissions[29].

## VIII. CHARACTERISTICS OF LLM-BASED TEXT-TO-IMAGE MODELS

Text-to-image models, which are based on machine learning, possess unique characteristics that set them apart from traditional computer vision or graphics applications. These outcomes are a result of the unique blend of natural language understanding and image processing.

#### A. Multimodal Understanding

These models have the ability to process and comprehend input from various sources, primarily text and images, by projecting them into a shared latent space. They have the ability to understand and interpret abstract and metaphorical descriptions, such as "a dreamscape of intricate cloud formations," and create meaningful visual representations.

#### B. Scalability and Transfer Learning

Modern language models have the advantage of transfer learning[92], where language understanding is pre-trained over vast amounts of data[55] (e.g., gpt, bert)[15] and then utilized for vision tasks. As the model becomes larger and more complex, both the parameters and the data used to train it improve, leading to even better performance. Models like dall•e 2 and imagen are built using complex architectures with millions of parameters, making them incredibly powerful.

#### C. Creativity and Diversity

Unlike rule-based or template-based systems, llm-based image generators can produce a wide range of diverse and unique outputs from a single prompt. The randomness introduced by stochasticity (through latent sampling) leads to novel and often surprising image outcomes.

#### D. Prompt Sensitivity and Customization

The quality of their output is heavily influenced by the choice of words, level of detail, and complexity of the input prompt. This results in the development of a new area of prompt engineering[9,79], where the user iteratively refines input prompts to enhance the model's ability to produce desired outputs.

#### E. Latent Space Manipulation

Many of these models operate in compressed latent space[1,3], such as vq-vae or latent diffusion, which allows for faster and more efficient generation. It also allows techniques like inpainting (filling in missing parts of an image)[77,81], outpainting (extending images)[76,83], and style mixing (combining different artistic styles)[19,18,82].

#### F. Shortfalls in Reasoning and Consistency

While having the capability to create, they often struggle with logical reasoning and spatial intelligence. The type of task where one is asked to describe the position of a red cube above a blue sphere to the left of a green cone will often result in a distorted or incorrect representation due to difficulties with precise spatial cognition.

#### IX. EXPERIMENTS AND RESULTS

A. Model	l Performa	псе Сотрс	irison				
Model CLIPScore $\uparrow$ tFID $\downarrow$ Creativity (1–10) Coherence (1–10)							
DALL•E-2	2 0.89	14.2	9.1	8.7			
Stable	0.81	16.5	8.3	7.8

Table 2: Energy Consumption of stable diffusion

# 2) Observations made in Table 1 & Table 2

The dataset assesses the environmental impact of the process of a few text prompts using artificial intelligence. It considers three prompts: "a bird flying in the blue sky," "bee on the flower," and "a toad on the stone." each function's energy -free consumption and co<sub>2</sub> emission are reported, including both aspects of the calculation and structured. The steps involve analyzing the energy consumption of the CPU and RAM, as well as the total electricity usage and the resulting emissions. In addition to the direct emissions, the total carbon footprint also takes into account the energy consumption for network, storage, cooling, and other overhead processes. Although simple, the instructions require some physical effort. The bird prompt requires the most energy and the highest coherence. This is likely due to the high level of processing or memory required for the task. CPU and RAM are similar, but the used energy zones have minor variations. These variations in calculations demonstrate that even small changes can have a significant impact on the emission levels. Bird prompt [] 9 ] sum calculate emissions for 0.005822 kg co. The bee and frog yielded 0.005731 kg and 0.005672 kg of co respectively. Although the differences are minimal, it is noteworthy on a larger scale. The emissions from the network remain consistent at 0.000100 kg co for all prompts. Storage and cooling emissions also show a slight variation. The seating arrangement in the pew changes slightly, with the bird prompt being the highest point again. This implies that the emissions from infrastructure are greater than the result of the system's design, rather than the nature of the task. Even minor tasks can have a substantial impact when executed on a large scale. Staying resilient is now more vital than ever. Techniques like quantization and model distillation can help decrease energy consumption. By implementing a carbon-vigorous timetable for cleaner energy, we can redistribute the workload and create a more sustainable future. Data centers must embrace renewable energy zones and implement efficient cooling systems. Real-time carbon monitoring tools can be environmentally conscious of free.

 Table 4: Energy Consumption of DALL.E

# 4) Observations of Table 3 & Table 4

This research examines the energy consumption and carbon emissions associated with large text-to-image models, focusing on stable diffusion xl and dallee. By using the same prompts, we analyzed how each model contributes to environmental impacts through compute emissions and energy usage. Stable diffusion had higher compute emissions, emitting 0.058603 kg of carbon dioxide for a single prompt, while dallee consumed 0.070414 kWh for the same process. Although expressed in different ways, these figures highlight the environmental consequences of generative ai[31]. By considering pue, cooling, network, and storage emissions, we find that the overall carbon cost rises, indicating that infrastructure plays a significant role in carbon emissions. Even seemingly small tasks, when considered on a global scale, can have a substantial impact on emissions. Consequently, it is crucial to optimize artificial intelligence models for sustainability. In order to avoid unnecessary costs, developers must utilize energyefficient hardware and employ carbon-conscious software techniques. By incorporating emissions monitoring into artificial intelligence systems, environmentally conscious options will gain a competitive advantage. Uniform benchmarks and incentives for low-carbon versions can steer the sector in the direction of more environmentally friendly practices. Future research should investigate the entire lifecycle of emissions, from training to deployment, in order to uncover hidden costs. Encouraging cloud service providers to be open about their operations and promoting the use of artificial intelligence on mobile devices can help reduce emissions. Collaboration across disciplines will be essential. AI innovation that is mindful of the environment can balance progress and responsibility. Lastly, the benefits of artificial intelligence are confronted with environmental concerns. Creating energyefficient, environmentally friendly models and systems can help ensure that artificial intelligence growth will not have a negative impact on our future.

# X. FUTURE SCOPE AND RESEARCH DIRECTIONS

The field of text-to-image synthesis using LLLMs is still in its early stages of development. Various promising avenues are being explored to enhance the reliability, controllability, and applicability of these systems across a broader spectrum.

1) Fine-Grained Control and Interactivity: Future systems will enable instantaneous user manipulation of power production. For instance, users can click on specific areas of an image to change colors or move objects without affecting the overall meaning or context. Combining the principles of learning with user interfaces and reinforcement learning[49] could potentially enable interactive creative workflows.

ISSN: 2321-9653; IC Value: 45.98; SJ Impact Factor: 7.538 Volume 13 Issue V May 2025- Available at www.ijraset.com

- 2) Multilingual and Cultural Adaptation: Expanding these models to accommodate multilingual prompts[46] and culturally relevant mentions[47] is a crucial goal. The more inclusive models will cater to the diverse creative and educational needs of people worldwide.
- 3) Integrating 3D and Video: Existing models are predominantly 2d static images. The future frontier lies in the development of text-to-3D[50] and text-to-video generation[53], where maintaining temporal consistency and spatial modeling becomes crucial. Initiatives like make-a-video and dreamfusion[51] are early attempts to move in this direction..
- 4) Personalized and Context-Aware Generation: Future systems would adapt to individual users' styles[54,75], preferences, or previous interactions. Context-aware generation that is aware of the ongoing conversation or project objectives would greatly enhance the personalization of these tools.
- 5) Ethical AI and Responsible Generation: As these models become integrated into creative and commercial workflows, ethical considerations[42] become crucial. This would entail marking AI-generated content[45] with watermarks, filtering out harmful prompts[43], and ensuring fairness[44] in representation across different demographic groups[37].
- 6) Hardware and Accessibility Innovations: It is difficult to implement these models on consumer-grade devices effectively due to their high computational cost. Thanks to advancements in edge computing[95], model pruning, and quantization[91], it will soon be feasible to execute simplified versions of models on smartphones[85] and virtual reality (VR) hardware.

# XI. CONCLUSION

The use of language models in generating images is a significant advancement in artificial intelligence, as it combines the ability to comprehend language with the capability to create visual representations. This research delves into the rapid growth of this sector, examining its technological advancements, dominant models, and real-world applications. While the outcomes are groundbreaking, there are still important matters to address regarding ethics, accessibility, and fairness. In the future, multimodal AI systems will become more interactive, manageable, and cooperative, transforming the way humans create and consume visual media.
