# MLR Study of IC50 values for Cephalosporin derivatives by MS Excel 

*Rajendra Kumar Sharma ${ }^{1}$, Arun Sikarwar1<br>1 Department of Chemistry, Government Home Science College, Hoshangabad-461001 (M.P.) INDIA•<br>rksharma210375@gmail.com

#### Abstract

: In this paper there is a study of multiple linear regression analysis (MLR) to develop a regression equation for prediction of $I C_{50}$ values of cephalosporin derivatives. $I C_{50}$ values are considered in their $-\log I C_{50}$ i.e. pIC $C_{50}$ terms. MLR is applied in stepwise regression analysis by means of forward selection method. 22 compounds of cephalosporin were selected for present study. 3D structures of these compounds were prepared with the help of chemsketch and saved as a mol file. Various indices like winer, detour, randic, harary, balban, schultz molecular topological indices, topological distance indices $T(N-N), T(N-$ S), $\boldsymbol{T}(\mathrm{N}-\mathrm{O})$, 3 D Morse indices, Sum of Keir-Hall electro topological state ( $S_{s}$ ), various combinations of 3D Morse and Keir Hall topological state, $\left(N_{S}\right)^{X}, a_{X X}$ were calculated with the help of Dragon software. The $I C_{50}$ values in terms of pIC $C_{50}$ were collected from literature. Then a stepwise regression analysis between $\mathrm{pIC}_{50}$ and selected indices was carried out by Microsoft excel software. A multiple linear regression equation was developed. There occurs strong correlation $\left(\boldsymbol{R}^{2}=0.642\right.$, pearson product moment correlation coefficient, $r^{2}=0.801$ ) between observed and predicted values of plC ${ }_{50}$ by developed regression equation. The developed equation/ model can be employed for suggesting some other cephalosporin molecules with improved $I C_{50}$ which can be proposed for further practical study/verification.

Keywords: MLR, topological distances, $\beta$-lactum antibiotic, 2D and 3D indices, pIC $_{50}$.

## INTRODUCTION

Cephalosporins are broad-spectrum antibiotics, applied for the treatment of bacterial infections caused by susceptible organisms. such as respiratory tract infections (pneumonia, strep throat, tonsillitis, and bronchitis), skin infections and urinary tract infections, surgical prophylaxis prevention of bacterial infection before, during, and after surgery, open, laparoscopic or endoscopic surgery intravenous prophylaxis etc.'s. They are sometimes given with other antibiotics. Cephalosporins [1] belong to class of $\beta$-lactum type antibiotic. $\beta$-Lactam antibiotics (beta-lactam antibiotics) are a broad class of antibiotics. Most $\beta$-lactam antibiotics work by inhibiting cell wall biosynthesis in the bacterial organism and are the most widely used group of antibiotics. Up to year

2003, in the view of sales, more than half of all commercially available antibiotics in use were $\beta$-lactam compounds. Penicillin and most other $\beta$-lactam antibiotics [2] act by inhibiting penicillin-binding proteins, which normally catalyze cross-linking of bacterial cell walls. In the absence of $\beta$-lactam antibiotics, the bacterial cell wall plays an important role in bacterial reproduction. Adding $\beta$-lactam antibiotics to the cell medium while bacteria are dividing will cause them to shed their cell walls and fail to divide, forming large, fragile spheroplasts.
$\beta$-lactam antibiotics are bacteriocidal [3], and act by inhibiting the synthesis of the peptidoglycan layer of bacterial cell walls. The peptidoglycan layer is important for cell wall structural integrity, especially in Gram-positive organisms, being the

## INTERNATIONAL JOURNAL FOR RESEARCH IN APPLIED SCIENCE AND ENGINEERING TECHNOLOGY (IJRASET)

outermost and primary component of the wall. The final transpeptidation step in the synthesis of the peptidoglycan is facilitated by transpeptidases known as penicillin-binding proteins (PBPs). PBPs vary in their affinity for binding penicillin or other $\beta$-lactam antibiotics.

Figure 1: Chemical structure of peptidoglycan molecule.

Core structure of cephalosporin and related structure property relationship can be shown by following diagram:

Figure 2: Structure-function relationships for cephalosporin core molecule
In the structure of cephalosporin as given in figure no. 2, nature of group -R and -X affects [4] activity as well as property of cephalosporin. Kinetic studies combined with absorption and nuclear magnetic resonance spectroscopy have shown the structure of the opening of the $\beta$-lactam ring of cephalosporyl. Cephalosporyl is the speices formed by the aminolysis of $\beta$-lactum ring of cephalosporin due to reaction with amino acid's amino group present in cell wall of bacterial cell wall. Opening of $\beta$-lactam ring takes place either in a concerted fashion or in some stages. The opening of the $\beta$ lactam ring leads to elimination of the group -X when this is configured as a leaving group. The process is well documented chemically and this property has been used as a strategy to obtain cephalosporins that can apply in a double action way. When the -X is conformed as the inactive form of the drug, the action of the $\beta$-lactam in the cephalosporin implies the release of the drug in situ. The cephalosporin nucleus can be modified to gain different properties by insertion of suitable -R group and -X group to obtain desirable activity/property. This task can be completed by QSAR/QSPR.

Material and methods:

QSAR/ QSPR i.e. Quantitative Structure Activity Relationship/ Quantitative Structure Property Relationship Studies for series of cephalosporin compounds consist the following steps:

1. To select accurate experimental physicochemical properties from compilations and studies
(i.e. from experimental or journal.)
2. To implement these properties and cephalosporin molecular descriptors to produce various

QSAR/ QSPR equations in terms of single or multiple regression equations [5], [6].

$$
\mathrm{Y}=\mathrm{aX}_{1}+\mathrm{bX} \mathrm{X}_{2}+\mathrm{cX}_{3}+\ldots \ldots+\mathrm{nX}_{\mathrm{n}}
$$

3. To determine the best QSPR equation on the basis of best prediction for each Physico-
chemical property.
4. To propose a model i.e. MLRM ( multi linear regression model).

Example of a QSAR/ QSPR model:

$$
\mathrm{Y}=\mathrm{aX}_{1}+\mathrm{bX} \mathrm{X}_{2}+\mathrm{c} \mathrm{X}_{3}+\ldots \ldots+\mathrm{n} \mathrm{X}_{\mathrm{n}}+\varepsilon
$$

Where, $Y=$ Physicochemical property as a dependent variable,
$\mathrm{X}_{1}, \mathrm{X}_{2}, \mathrm{X}_{3}, \ldots \ldots \ldots . . \mathrm{X}_{\mathrm{n}}=$ Specific molecular descriptor as independent variables.
$\mathrm{a}, \mathrm{b}, \mathrm{c}, \ldots \ldots \mathrm{n}=$ Regression constants., $\varepsilon=$ Error
When correlation is not strong between dependent and independent variable then any single independent variable can not be used for satisfactory prediction of dependent variable. So multiple linear regression analysis is to be applied to increase correlation by adding suitable one or more indices in various steps. This can be done in two ways [7], [8] -
(a) By forward selection method, in which each variable index is added in various steps one by one in regression analysis. In each step variable index is selected on the basis of lowest P value. Regression ansalysis is carried out till the step at which all variable appears significant $(\mathrm{P}<0.05)$ in any one or more regression equation.
(b) By backward selection method, in which initially all variable indices are taken in regression analysis and variable indices are removed in step by step. Removal is done on the basis of P-value. In each step the variable index, whose removal results in highest significant regression equation, is removed.

Various molecular descriptors choosed for selected set of molecular structure of cephalosporin type drugs and calculated

## INTERNATIONAL JOURNALFOR RESEARCH IN APPLIED SCIENCE AND ENGINEERING TECHNOLOGY (IJRASET)

with the help of Dragon software [9]. For this purpose 2D and 3D structures prepared by Chem sketch [10] and saved in the form of mol. files. Then some physico-chemical properties calculated by above software. The pharmacological property (activity) collected from reliable cheminformatics sources. Stepwise regression analysis was carried out for modeling the physico-chemical and pharmacological properties (activity) with the help of selected descriptors by Micro soft office 2007 software [11]. A regression equation and hence a regression model was developed. Then each physico-chemical and pharmacological property were predicted with the help of respective developed regression equations. Importance of regression equation was tested by calculating the correlation between observed and predicted values. Correlation between observed and predicted values were expressed by means of simple $\mathrm{R}^{2}$, Adjusted- $\mathrm{R}^{2}$, pearson product moment correlation coefficient $\mathrm{r}^{2} \equiv \mathrm{r}, \quad$ PRESS. The detailed information of selected molecules for present study is given in table no. 1 as follows:

Table no. 1 Structure of selected molecules for the study

| 宏 | Name | Structure of molecule | $\stackrel{\rightharpoonup}{\sim}$ | Name | Structure of molecule |

A description of selected pharmacological property (activity) are as follows:

## Half maximal Inhibitory Concentration $\left(\mathrm{IC}_{50}\right)$ :

It is a measure of the effectiveness of a compound in inhibiting biological or biochemical function. Often, the compound in question is a drug candidate. This quantitative measure indicates how much of a particular drug or other substance (inhibitor) is needed to inhibit a given biological process (or component of a process, i.e. an enzyme, cell, cell receptor or microorganism) by half. The $\mathrm{IC}_{50}$ [12] of a drug can be determined by constructing a dose-response curve and examining the effect of different concentrations of antagonist on reversing agonist activity. $\mathrm{IC}_{50}$ values can be calculated for a given antagonist by determining the concentration needed to inhibit half of the maximum biological response of the agonist.

Figure 3: Illustration of $\mathrm{IC}_{50}$ by graph.
$\mathrm{IC}_{50}$ is not a direct indicator of affinity although the two can be related at least for competitive agonists and antagonists by the following Cheng-Prusoff equation [13]:

$$
\mathrm{K}_{\mathrm{i}}=\mathrm{IC}_{50} /\left\{1+\left([\mathrm{S}] / \mathrm{K}_{\mathrm{m}}\right)\right\}
$$

## INTERNATIONAL JOURNALFOR RESEARCH IN APPLIED SCIENCE AND ENGINEERING TECHNOLOGY (IJRASET)

Where, $\mathrm{K}_{\mathrm{i}}$ is the binding affinity of the inhibitor, $\mathrm{IC}_{50}$ is the functional strength of the inhibitor, $[\mathrm{S}]$ is substrate concentration and $K_{m}$ is the affinity of the substrate for the enzyme. Whereas the $\mathrm{IC}_{50}$ value for a compound may vary between experiments depending on radioligand concentration, the $\mathrm{K}_{\mathrm{i}}$ is an absolute value. $\mathrm{K}_{\mathrm{i}}$ is the inhibition constant for a drug. The concentration of competing ligand in a competition assay which would occupy $50 \%$ of the receptors if no radioligand were present. $\mathrm{IC}_{50}$ values can be determined through journal searching and cheminformatics as wel as estimated also by various softwares calculations available online or in purchased version. These softwares require 3D structures of considered molecules.

Brief descriptions of selected descriptors [14], [15], [16] are as follows:

Wiener Index (W): Wiener index (also Wiener number, introduced by H.Wiener in 1947) is a topological index of a molecule, defined as half the sum of the numbers of edges in the shortest path in a chemical graph between all pairs of nonhydrogen atoms in a molecule. Chemical graph or molecular graph is the collection of points and lines connecting these points. This index was introduced by H. Wiener in 1947 Wiener index may be calculated using distance matrices.
Harrary Index (H):Harrary Index $H$ is defined as half sum of the element of the inverse distance matrix.

$$
\mathrm{H}=\frac{1}{2} \sum_{\mathrm{i}=1}^{\mathrm{j}=1}\left(\mathrm{~d}^{-1}\right)_{\mathrm{ij}}
$$

Where, $\left(\mathrm{d}^{-1}\right)_{\mathrm{ij}}=\mathrm{ij}$ th element of inverse distance matrix.
Schultz Molecular Topological Index (SMTI): This index was given by Harry P. Schultz,

SMTI is defined as the summation of all the terms obtained by multiplying valence row matrix (V) to sum of adjacency matrix (A) to distance matrix (D).

$$
\mathrm{SMTI}=\sum_{i=1}^{\mathrm{N}}[\mathrm{~V}(\mathrm{~A}+\mathrm{D})]
$$

Randic Index (X): This Index was proposed by Randic in 1975 and shows the effect of vertices i.e. shape of molecule over properties and activity. This is defined as summation of all terms obtained by taking inverse root of each term's derived by multiplication of coloumn and horizon element of matrix for connectivity. $\quad \mathrm{X}=\sum\left[\mathrm{d}_{\mathrm{i}} \mathrm{d}_{\mathrm{i}}\right]^{-\frac{1}{2}}$
$d_{i}, d_{j}$ are valences of vertices $i$ and $j$ which is equal to number of bonds connected to atom $i$ and $j$.

Balban Index (J):

$$
\mathrm{J}=\left[\frac{\mathrm{M}}{(\mu+1)}\right] \sum\left(\mathrm{D}_{\mathrm{i}} \mathrm{D}_{\mathrm{i}}\right)^{-1}
$$

$\mathrm{M}=\mathrm{No}$. of bonds (edges).
$\mu=$ Cyclometric no.
$D_{i} D_{j}=$ Sum of row $i$ coloumn $j$ of a distance matrix respectively.

## Detour Index (W')

It is half the sum of all matrix elements present in Detour matrix (DD). Entries of the Detour matrix (DD) represent the maximum topological distances between two given vertices.

$$
\mathrm{W}^{\prime}=\frac{1}{2} \sum_{\mathrm{i}, \mathrm{j}}^{\mathrm{N}_{\mathrm{SA}}} \mathrm{dd}_{i j}
$$

$\mathrm{dd}_{\mathrm{ij}}$ - the number of bonds in the longest path connecting the pair of atoms $i$ and $j$
$\mathrm{N}_{\mathrm{SA}}$ - the number of non-hydrogen atom in the molecule. This was first introduced by Harary in 1969, in the context of Graph theory. When there is no cycle present in the considered molecular structure, the distance and the detour matrixes are identical. This can characterize one or more rings in the molecule. Detour matrix has been proposed as a tool to characterize cyclic structures.

T(N-O): Sum of Topological Distances between Nitrogen and Oxygen atom.

T(N-N): Sum of Topological Distances between Nitrogen and Nitrogen atom.

T(N-S): Sum of Topological Distances between Nitrogen and Sulphur atom.

Topological Distances used in $\mathrm{T}(\mathrm{N}-\mathrm{O}), \mathrm{T}(\mathrm{N}-\mathrm{N}), \mathrm{T}(\mathrm{N}-\mathrm{S})$ :
This was given by Bonchev (1991) Trinajstic (1992). Let $\left\{\mathrm{x}_{1} \ldots \mathrm{x}_{\mathrm{k}}\right\}$ be the atoms of a particular chemical element x in the molecule. Similarly, $\left\{y_{1} \ldots y_{m}\right\}$ are the atoms of a

## INTERNATIONAL JOURNALFOR RESEARCH IN APPLIED SCIENCE AND ENGINEERING TECHNOLOGY (IJRASET)

particular chemical element $y$ in the molecule. We permit the case of $x=y$ as well. Then the atom pair topological distance between the chemical elements $x$ and $y$ is given by:

$$
\frac{1}{2}\left(\sum_{i=1}^{k} \cdot \sum_{j=1}^{m} \mathrm{~d}_{\mathrm{ij}}\right)
$$

where, $\mathrm{d}_{\mathrm{ij}}$ is the topological distance between $\mathrm{x}_{\mathrm{i}}$ and $\mathrm{y}_{\mathrm{i}}$.

## 3D MoRSE Descriptors:

3D MoRSE descriptors (3Dimensional Molecule Representation of Structures based on Electron diffraction) are derived from infrared spectra simulation using a generalized scattering function. A typical MoRSE descriptor is denoted by Mor (sw), where s and w take the values $1 \leq \mathrm{s} \leq 32$ and

$$
w \varepsilon(u, m, v, e, p)
$$

where, $u$ is unweighted

$$
\mathrm{m} \text { is weighted by mass }
$$

$v$ is weighted by van der Waals volume
$e$ is weighted by electronegativity
p is weighted by polarizability
The MoRSE descriptor is defined as follows:

$$
\operatorname{Mor}(\mathrm{s}, \mathrm{w})=\mathrm{I}(\mathrm{~s}, \mathrm{w})=\sum_{i=2}^{n} \sum_{\mathrm{i}=1}^{\mathrm{i}=1} \mathrm{w}_{\mathrm{i}} \mathrm{w}_{\mathrm{i}} \sin \left(\mathrm{sr}_{\mathrm{ij}}\right) /\left(\mathrm{sr}_{\mathrm{ij}}\right)
$$

where, $\mathrm{r}_{\mathrm{ij}}$ is the Euclidean distance between the atoms $i$ and $j$, and $w_{i}$ and $w_{j}$ are the weights of the atoms $i$ and $j$ respectively.

Keir and Hall valence connectivity indices: The molecular connectivity valence delta-values have been defined in terms of the count of no hydrogen. Non valence electrons on a valence-state atom as screened from the nucleus by the core electrons.
$Z_{k}$ - Total number of electrons present on atom $k$.
$Z_{k}^{\mathrm{V}}$ - Number of valence electrons in the $\mathrm{k}^{\text {th }}$ atom
$\mathrm{H}_{\mathrm{k}}$ - Number of hydrogen atoms directly attached to the $\mathrm{k}^{\text {th }}$ non-hydrogen atom
$\mathrm{m}=0$ - Atomic valence connectivity indices
$m=1$ - One bond path valence connectivity indices
$\mathrm{m}=2$ - Two bond fragment valence connectivity indices
$\mathrm{m}=3$ Three contiguous bond fragment valence connectivity indices etc.

Valence connectivity for the $\mathrm{k}^{\text {th }}$ atom in the molecular graph,

$$
\delta_{\mathrm{k}}^{\mathrm{v}}=\frac{\left(\mathrm{z}_{\mathrm{k}}^{\mathrm{v}}-\mathrm{H}_{\mathrm{k}}\right)}{\left(\mathrm{Z}_{\mathrm{k}}-\mathrm{Z}_{\mathrm{k}}^{\mathrm{V}}-1\right)}
$$

Above all descriptors [17], [18] some other indicator indices representing the no. of particular atom in particular group or structure like no. of S atoms in group -X etc.s are also counted and applied in MLR. The combination of 3D Morse and sum of Keir hall topological distances are applied shown in table no. 4 Other indices like $\left(\mathrm{EN}_{\text {orb. }}\right)^{*} \mathrm{O}=\mathrm{C}<$, Donar sites and $\alpha_{\mathrm{XX}}$ calculated by Dragon shown in table no. 5 considered for MLR analysis. For determining microscopic contribution of group -X the common indices like $\mathrm{W}, \mathrm{H}, \mathrm{X}^{1}, \mathrm{~W}^{\prime}, \mathrm{T}(\mathrm{N}-\mathrm{N})$, $\mathrm{T}(\mathrm{N}-\mathrm{S}), \mathrm{T}(\mathrm{N}-\mathrm{O})$ also calculated for selected set of molecules by removing -R group as shown in table no. 7

## Experimental:

$\mathrm{IC}_{50}$ values in terms of $\mathrm{pIC}_{50}$ values searched out from literature. Selected molecules 2D and 3D structures were prepared by chem sketch software and saved in mol file formate. The various molecular descriptors were calculated by Dragon software (given in table no. 2, 3, 4, 5, 6 and 7)

In order to derive relationship of dependent variable (activity/ property) and independent variables (descriptors/ indices) different approaches for QSAR have been offered in the literature. These approaches range from simple linear regression (LR) and multiple linear regression trained by a variety of methods. MLR techniques can be used to determine the most relevant features for a given model.

Multiple regression carried out by MS excel 2007 through the method (a) out of above discussed methods.

Figure 5: $\quad$ Distribution of selected indices with $\mathrm{pIC}_{50}$

## CONCLUSIONS:

From the developed equation this can be concluded that $\mathrm{IC}_{50}$ value is predicted by $\left(\mathrm{N}_{\mathrm{S}}\right)^{\mathrm{X}}$ in larger proportion than others. Since, $\left(\mathrm{N}_{S}\right)^{\mathrm{X}}$ appears in negative contribution so to decrease $\mathrm{pIC}_{50}$ no. of S atoms in group -X of cephalosporin core structure should be minimized and vice versa. However, T(NS) appears in positive factor so to increase $\mathrm{pIC}_{50}$ sum of topological distances between nitrogen and sulphur should be maximized. Another fact which should be considered during designing of new molecule may be that for larger $\mathrm{pIC}_{50}$ new molecule. However, polarizibility in XX direction also helpful till little extent to propose new molecules with desired $\mathrm{IC}_{50}$ value.
