Abstract: To improve overall system performance and reduce dispersion, several compensation technologies are proposed. In this paper we have studied about the dispersion compensation scheme in WDM system. Dispersion Compensation Scheme (DCF) and Fiber Bragg Grating (FBG) are the widely used dispersion compensating techniques for optical communication. Here a 16 channel optical network is used with two dispersion compensators i.e DCF and FBG. This paper gives idea about both the compensators as we have done comparison between the two using different parameters that inclines Q-factor and BER. We have done simulation for both the compensating methods for the length 120km, 140km and 150 km and data rate 80 gbps and 120 gbps with the help of Optisys 14.0 software and we have included the diagram for simulation setup, the simulation graph and the comparison graph of different parameters for better comparison

Keywords: DWDM, FBG, Dispersion, DCF, EDFA, BER, Q factor

I. INTRODUCTION

One of the most efficient techniques to increase the information carrying capacity of an optical fiber communication is wavelength division multiplexing. In WDM, the information carrying capacity can be further enhanced by increasing either the per-channel data rates or the number of multiplexed channels. This phenomenon is described by the term DWDM.

Dense wavelength division multiplexing is a fiber optic transmission technique that employs light wavelength to transmit data parallel by bit or serial by character. DWDM can be used to enabling service provides to accommodate consumer demand for ever increasing amounts of wavelength. As we know that transmission in WDM optical network is affected by attenuation, chromatic dispersion, polarization mode dispersion and the fiber non-linear effect at high bit rate and the power level. Here we are using the technique of DWDM, so we have used optical amplifiers like Er doped fiber amplifier (EDFA) as all the channels need to be amplified simultaneously. We are transmitting the signal in optical fiber, the dispersion compensation is the prior issue. Dispersion is the spreading of light pulse as it travels down the length of an optical fiber. Dispersion limits the bandwidth or information carrying capacity of a fiber. Due to dispersion, optical pulse broadens as they travel in single mode fiber. The bit-rates must be low enough to ensure that pulses are farther apart and therefore the greater dispersion can be tolerated. To compensate dispersion in these system various methods can be implemented which are microchip compensation, optical phase conjugation, initial pre chip compensating fiber, fiber bragg grating (FBG) etc.

We have considered the two dispersion compensation methods in this paper that are DCF and FBG and made comparison to find out which method is best for dispersion compensation.

A. Fiber Bragg Grating

A fiber bragg grating is a type of distributed bragg reflector constructed in short segment of optical fiber that reflect particular wavelength of light and transmits all other. This is achieved by creating a periodic variation in the refractive index of the fiber core which generates a wavelength specific dielectric mirror. A fiber bragg grating can therefore be used as an inline optical filter to block certain wavelength or as a wavelength-specific reflector.

The fundamental principle behind the operation of an FBG is fresnel reflection, where light travelling between media of different refractive indices may both reflect and refract at the interface.

The refractive index will typically alternate over a defined length. The reflected wavelength (λ), called the bragg wavelength is defined by the relationship.

$$\lambda_B = 2n\lambda$$

where n is the average refractive index of the grating.

Fig 1 FBG compensate for dispersion by reflecting different wavelengths at different locations along the grating lengths.

B. Dispersion Compensating Fiber

To improve the overall system performance and reduce the losses as much as possible several dispersion compensation techniques are used.

The using of DCF were more suitable because components of DCF are more stable, not easily affected by the temperature, wide bandwidth, DCF has become a most suitable method for dispersion compensation. The use of DCF is an efficient way to reduce overall dispersion in WDM.

There is a positive second order and third order dispersion in a single mode fiber, while the DCF dispersion value is negative. So by inserting a DCF the average dispersion is close to zero

Dispersion compensating fiber have a high negative dispersion -60 to -100 ps/nm km and used to compensate the positive dispersion of transmission fiber

Dispersion compensation is done by three different scheme depending upon the position of DCF.

In pre compensation the DCF is place before the standard SMF to compensate the positive dispersion in standard SMF

In post compensation the DCF is placed after the standard SMF to compensate the positive dispersion in standard SMF.

In symmetrical, both the combination of pre and post symmetric were used i.e. DCF is placed before as well as after the standard SMF to achieve the dispersion compensation.

Fig 2:- Different dispersion compensation schemes

II. SIMULATION SETUP

The 16 channel WDM optical network were designed using opti system 14.0 simulation software. We have simulated post DCF and FBG at 80, 100 & 120 gbps .Data rate and the results were compared for various length of optical fiber. In the simulation, the transmitter section consist of pseudo random bit sequence generator which consist of data source at 5 & 7.5 gbps per channel.

NRZ pulse generator converts the binary data into electrical pulses that modulates the laser signal through Mach-zehnder (MZ) modulator. MZ modulation has two i/p pins & one o/p pins. The transmitter section block diagram

Fig1. Simulation setup of dcf

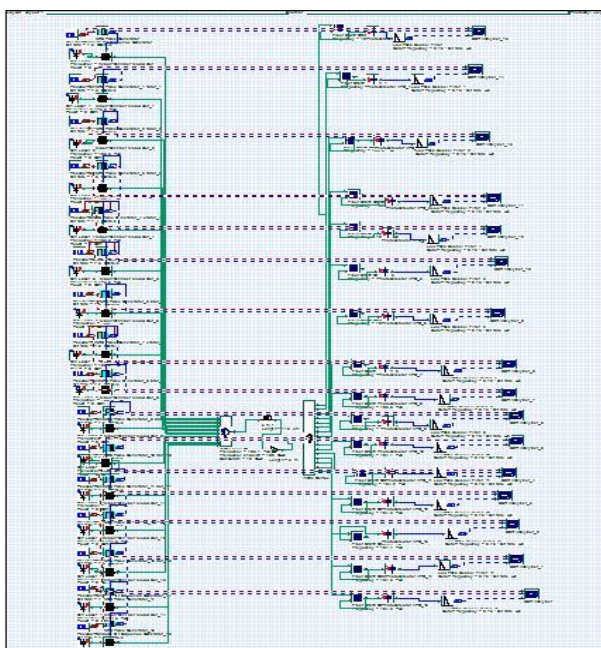

Fig2. Simulation setup of fbg

There are 16 laser sources generating optical signal of different wavelength, the channel spacing use is 0.1 THz with 0db output power.

The multiplexer consists of 16 input channels and transmitted over optical fiber channel. The transmitted channel consists of a SMF of variable length of 80,100 & 120 km and DCF of length 20 km. EDFA fiber of length 5 km are used after the DCF in order to amplify the signals.

At the receiver sides, the 1:16 demux is used to slot the signal in 16 different channels. The o/p of the demux is given to photo detector APD which converts the optical signal to electrical. Then the electrical signal is passes through low pass bessels filter having transfer function

$$H(s) = \frac{\theta_n(0)}{\theta_n(s/\omega_0)}$$

where $\theta_n(s)$ is a reverse [Bessel polynomial](#) from which the filter gets its name and ω_0 is a frequency chosen to give the desired cutoff frequency. The filter has a low-frequency group delay of $1/\omega_0$. Since $\theta_n(0)$ is indeterminate by the definition of reverse Bessel polynomials, but is a removable singularity, it is defined that $\theta_n(0) = \lim_{x \rightarrow 0} \theta_n(x)$

RESULTS AND ANALYSIS

The two dispersion compensation methods have been analyzed at 80 Gbps and 120 Gbps for WDM network in terms of bit error rate (BER) and Q-factor. In order to carry out various simulations, Optisys 14.0 software has been used. We have carried out the simulations for 80 gbps and 120 gbps for 120 km, 140 km and 150 km. We have tabulated the simulated results of Q-factor and BER accordingly.

III. CONCLUSION

In this paper, we have analyzed the 16 channel WDM system at 80 Gbps and 120 Gbps for the two different dispersion compensation methods using DCF & FBG and are compared in terms of BER and Q-factor. It was observed from simulation and results that DCF gives better performance for wide band signal whereas FBG is preferable for narrowband signals. In conclusion it is found that dispersion compensation is necessary to reduce losses and cost of the system. DCF techniques increase the total losses due non-linear effects and costs of optical transmission system where as FBG helps in decreasing the cost of the system and also have low insertion loss but have limited range. Hence we can conclude both have their advantage and disadvantage and both can be used as per the requirements to compensate dispersion.
