Abstract: The present study was carried out to identify the status of avifauna at water reservoir in Kekri, a small city of Ajmer district of Rajasthan state. Observation suggested that total 53 species of birds belong to 16 families were found in the study area. Out of 53 species 25 were resident, 27 winter visitor, and only 01 species were found passage migrant. Keywords: Kekri, avifauna, water birds, biodiversity threats.

I. INTRODUCTION

Biodiversity at present is better understood for birds in many respects than any other major group of organisms because they probably inspire more extreme interest in humans, are often spectacular, relatively easily observed and not too cryptic to identify. Diversity of avifauna is one of the most important ecological indicators to evaluate the quality of habitats (Bhadja and Vaghela, 2013). Wetlands are transitional zones between permanently aquatic and dry terrestrial eco-systems. Birds serve as one of the best environmental indicators. Their presence anywhere speaks volumes of the environment as to whether all is well or there is something amiss. The presence of birds also shows the biological importance or going technical, the biodiversity significance of an area (Harney and Bhute, 2014). During the last few decades considerable studies on avifauna diversity from different freshwater bodies of India have been carried out by researchers like, Kannon (1980), Davidar (1985), Mujumdar (1985), Newton et al. (1986), Jhingram (1988), Ghosal (1995), Rathore and Sharma (1999), Yardi et al. (2004), Kulkarni et al. (2005), and Kumar (2006), Donar et al. (2012). However very little information is available about status of aquatic avifaunal status of Kekri (Ajmer), Rajasthan. Therefore, the present study provides a comprehensive check-list of birds to identify the status of aquatic avi-faunal diversity of Kekri located in the Ajmer District of Rajasthan State.

II. MATERIALS AND METHODS

Study location: The present study of aquatic avifauna was studied in Kekri and nearby places (Kohda and Chand Thali), parts of District Ajmer of Rajasthan state. It is situated 80 Km far from Ajmer and 130 Km from Jaipur Capital of Rajasthan. Its coordinates are 25°58'29.40" North and 75°09'10.71" East. Elevation is 1188 ft. The average maximum temperature is 41°C during the month of May, where average minimum temperature is 9°C during the month of January.

III. METHODOLOGY

To achieve the proposed objectives, different water bodies of Kekri were visited fortnightly in the morning (06:00 to 10:00 hrs) and later in the evening (15:00 to 18:00 hrs), using line transect method (Gaston, 1975; Sales and Berkmuller, 1988) and point count method (Altman, 1974). Birds were observed within the transect of 300m. Instruments digital camera and binocular were used during the study for observing birds. Birds were photographed under Camera Quadrate Method (Meena and Kachhawa, 2015) and were subsequently identified using "A pocket guide of the birds of the Indian subcontinent" by Grimett et al. (1999) and Manakkadan and Pittie (2001). The threats and conservation issues were also identified by field visits and observation of wetlands

IV. OBSERVATION AND RESULT:

Results of the filed observation suggested that total 53 species of birds belong to 16 families were present in the study area. Out of total 53 bird species; 45 species were found least concern, 05 species Aythya nyroca (Güldenstädt, 1770), Mycteria leucocephala (Pennant, 1769), Limosa limosa (Linnaeus, 1758), Sterna aurantia (Gray, JE, 1831) and Threskiornis melanocephalus (Latham, 1790) near threatened, 02 Aythya ferina, (Linnaeus, 1758) and Pelecanus crispus (Bruch, 1832) vulnerable. Mesophoyx intermedia (Wagler,1827) is mentioned in red data list but not assessed. According to IUCN red list criteria version 3.1, 25 bird species resident, 27 winter visitor, 01 species Phoenicopterus roseus, (Linnaeus, 1758) passage migrant. Population trend of 28 species decreasing, 07 species increasing, 17 species stable and 01 unknowns. Detail observations have been mentioned in table as Cheklist of Water birds

V. DISCUSSION

From the above results it could be made out the availability of water, safe habitat and food sources for both common and migratory birds around the water bodies are important for the occurrence and abundance of aquatic bird populations. However, major threats found in study area were. Area under investigation is highly influenced by soil mining, water mining, deforestation, urbanization and Anthropogenic activities along with agricultural practices, grazing, collection of forestry items (wood and plant products). These activities having high level of negative effect on ecologically important species those inhabiting area under investigation. Thus we recommend forest department or other officials to restrict these activities at a level of local inhabitant
