Abstract: Though the expenditure of world energy is increasing exponentially, it is obvious that a solution of renewable energy must be utilized. In order to fulfill the energy demand of the mankind, utilization of the huge energy of the sun by transforming it into electricity is an emerging alternative way. Recently developed InGaN is a direct band gap solar photovoltaic material that has an amazing tunable band gap of 0.7 eV to 3.4 eV and a high optical absorption coefficient over 10⁶/cm. In this paper, numerical simulations has been done using MATLab to explore the unknown potential of this promising material to design a high performance InGaN solar cell. All the required parameters for simulation were determined from the theory, literature and in some cases reasonable estimation. This simulation were done with different ratio of In and Ga content for the single junction solar cell and found a high conversion efficiency of 27.3% with this InGaN compound material.

Keywords: Renewable energy; Solar photovoltaic; InGaN; MATLab; Conversion efficiency.

I. INTRODUCTION

Worldwide civilization requires low-priced, dependable and sustainable energy sources. With the increased technological development, the energy expenditure has enlarged steadily. More and more energy consumption is expected in future to withstand the present human development. Solar cell is the best way to utilize energy from the sun that is exactly the boundless source of renewable and clean energy. The initial efforts for progress of photovoltaic (PV) cells were focused towards space applications, and PV cells are still today the main source of power in space. InGaN based PV cells are the most potential candidate for solar energy conversion into electricity as there are possibilities of higher cell conversion efficiency and low cost fabrication. InGaN has near the ideal band gap of 0.7 eV to 3.42 eV [1, 2, 3] and higher optical absorption coefficient greater than 10⁶/cm, which indicates the better absorption of the sun spectrum. It is a very potential material for ultra-thin solar cells in space application.

The layers of an InGaN solar cell might be deposited using the various techniques, namely Metal Organic Chemical Deposition (MOCVD), Molecular Beam Epitaxy (MBE), Metal Organic Vapor Phase Epitaxy (MOVPE) [4]. In 2007, Xiaobin Zhang published the conversion efficiency of single junction InGaN solar cell was 20.284% [5] and the same group published the efficiency of 24.95% in 2008 [6]. In 2011, S. Ben Machiche has achieved efficiency of 24.88% for a single junction InGaN solar cell [7]. The III-V group materials are widely used for tandem materials cells for the space application, in 2009 InGaP/GaAs double Junction and InGaP/GaAs/Ge triple Junction cells were designed. Triple junction structure of GaInP/GaAs/Ge shown efficiency of 41.6% [8] but itsshouldbenotethatthe0.66eV indirect band gap energy of Geisnotoptimial band gappower sub cellofa triple junction cell. In recent times, in 2012 a latest structure of GaInp/GaAs/GaInNAs shows efficiency of 44%, which is the world highest [9]. But the problem of this structure is more complex quardinary alloy system of the cell and the toxicity and the cost of As material are the biggest barrier of these material system.

However, there were no major work using MATLab with this excellent material though it can save time and cost by designing high efficient cell. There are scopes to minimize the thickness to save materials and to increase the conversion efficiency with improved short circuit current density (Jsc), open circuit voltage (Voc) and fill factor (FF) with different proportion of In(x) in InxGa1-xN material system [10]. All the above ideas were modeled in this work and numerical analysis was done by using MATLab to achieve the best possible structure of InGaN single junction solar cell for higher efficiency which is the basic component of tandem solar cell. The conversion efficiency has been found in this research work were 27.3% for the single junction solar cell from MATLab Simulation.

II. MODELING AND MATLAB SIMULATION

Numerical simulation is the first way to calculate the effect on cell performance [10] and to test the possibility of the proposed structure. Modeling is widely used in the analysis of solar cells due to its complex and very costly fabrication method. Figure 1 illustrates the proposed structure of a InGaN based single junction solar cell. From Figure 1, it is clear that this structure consists a p
layer and an n layer InGaN along with a TCO and back contact to achieve thin InGaN layer. MATLAB simulations were done in this work to design the cell structure and the required equations were collected from the theory of solar cells. The equations required for this simulations are shown here.

The Short circuit current density, $J_{sc} = J_{p}^n + J_{p}^p$ [11]. Where $J_{p}^n$ and $J_{p}^p$ are the photocurrent collected by p type and n type materials.

The total the photocurrent collected by p type material is equal to

$$J_{p}^p = \int_{\lambda_1}^{\lambda_2} J_{p}^p(\lambda) d\lambda$$

Where $\lambda_1$ is the absorption wavelength of InGaN which can be varied from 0.7 eV to 3.4 eV. The photo generated electron current density is

$$J_{p}^p(\lambda) = qF(\lambda)[1 - R(\lambda)] \frac{a_p(\lambda)}{\alpha_p(\lambda)} \left[ b_p + a(\lambda) - \exp\left(\frac{-Z_p \alpha_p(\lambda)}{L_p}\right) \right] \left[ b_n + a_n(\lambda) \cosh\left(\frac{Z_n}{L_n}\right) + \frac{1}{2} b_n a_n(\lambda) \sinh\left(\frac{Z_n}{L_n}\right) \right]$$

Where $q$ is the absolute value of electronic charge,

$$\beta_n = [\cosh(\frac{Z_n}{L_n}) + b_n(\frac{Z_n}{L_n})].$$

The spectral distribution of the solar flux is

$$F(\lambda) = 3.5 \times 10^{-12} \lambda^{-2} \left[ \exp\left(\frac{hc}{kT_1 \lambda} - 1\right) \right]^{-1}$$

Where $h$ is plank’s constant, $c$ is the velocity of light. For n type material, total photocurrent collected is

$$J_{n}^p = \int_{\lambda_1}^{\lambda_2} J_{n}^p(\lambda) d\lambda$$

Where $\lambda_1$ is the absorption wavelength of InGaN which can be varied from 0.7 eV to 3.4 eV. The photo generated electron current density is

$$J_{n}^p(\lambda) = qF(\lambda)[1 - R(\lambda)] \frac{a_n(\lambda)}{\alpha_n(\lambda)} \left[ b_n + a(\lambda) - \exp\left(\frac{-Z_n \alpha_n(\lambda)}{L_n}\right) \right] \left[ b_p + a_p(\lambda) \cosh\left(\frac{Z_p}{L_p}\right) + \frac{1}{2} b_p a_p(\lambda) \sinh\left(\frac{Z_p}{L_p}\right) \right]$$

Where,

$$\beta_p = [\cosh(\frac{Z_p}{L_p}) + b_p(\frac{Z_p}{L_p})].$$

---

**Fig. 1** Proposed structure of single junction solar cell
Open circuit voltage $V_{oc}$ is defined as

$$V_{oc} = \frac{KT}{q} \ln \left( \frac{J_0}{J_p} + 1 \right)$$ \[12\]

Where $J_0$ is the reverse saturation current and the equation is,

$$J_0 = \frac{q}{\tau_e} \left( \frac{p_n}{n_p N_A} + \frac{p_e}{n_n N_D} \right) n_i^2$$ \[13\]

Where

$$n_i^2 = N_c N_p \exp \left( -\frac{E_g}{KT} \right)$$

$N_c$ and $N_p$ are the effective density of state. $N_A$ and $N_D$ are the doping concentration of p type and n type materials. The equation of mobility of electron is

$$\mu_e(N) = \mu_{min} + \frac{n_{max} - n_{min}}{N_c + N_p}$$ \[14\]

The equation of fill factor is [15]

$$FF = \frac{v_{oc} - \ln(v_{oc} + 0.72)}{v_{oc} + 1}$$

where, $v_{oc} \approx \frac{q}{n \eta T} V_{oc}$ $n$ is the ideality factor that can be considered 1.

Finally the efficiency of a solar cell is related with short circuit current density, open circuit voltage and fill factor of a cell.

$$\eta = J_{sc} V_{oc} FF$$

The power input is 1000 W/m$^2$ at 1 sun.

Table 1 show all material parameters used in this modeling, which were determined based on literature, theory or in some cases reasonable estimations to get better cell performance.

III. RESULT AND DISCUSSION

The number of parameters that can be varied is more than 50 in a solar cell. So it is ambiguous to solve such variable model. This numerical analysis has been done aiming to improve the cell performance of the InGaN single junction solar cell structure. All the required equations were simulated using MATLAB to find the stable structure of a single junction InGaN solar cell. The dependency of the cell performance on the ratio of In in In$_{1-x}$Ga$_x$N from 0% to 100% has been simulated by MATLAB. It has been observed from the simulation result shown in Figure. 2 that the efficiency is highest in the range of Indium ratio of 55% to 75% corresponding the following equation of band gap with Indium proportion. [16, 17]
\[ E_g(x) = 0.7x + 3.4(1 - x) - 1.43x(1 - x) \]

Where \( E_g \) is the band gap and \( x \) is the proportion of In in In\(_x\)Ga\(_{1-x}\)N.

Figure 2. Efficiency vs percentage of In in InGaN of the proposed single junction solar cell

![Efficiency graph](image)

Figure 3. J-V curve of the proposed InGaN single junction solar cell

![J-V curve](image)

Figure 3 shows the output J-V characteristic curve of the designed cell. After doing rigorous simulation, efficiency of 27.3% was found (\( J_{sc}=34.15\text{mA/cm}^2, V_{oc}=0.89\text{V} \) and \( FF=0.88 \)). MATLAB is more effective tools that requires less time to simulate more data. Rigorous simulation can be done from which best result can be fitted. In AMPS, for each data we need to simulate the cell separately. But in MATLAB, it can be done by using the equation with the range of data and then best cell structure can be selected.

### III. CONCLUSION

In this paper, a single junction solar cell of InGaN material has been designed. MATLAB is introduced to design such kind of solar cell. Though the fabrication method of this cell is very complex and costly, MATLAB simulation is very useful to design this highly efficient cell. Simulation were done with different ratio of In and Ga (0-100%) content in InGaN for a single junction solar cell and got highest conversion efficiency of 27.3% (\( J_{sc}=34.15\text{mA/cm}^2, V_{oc}=0.89\text{V}, FF=0.88 \)) at 66% of In in InGaN. Multijunction tandem solar cells can be designed from this basic cell of InGaN and it would be an attractive solution for space application.
