Comparative Analysis of Various Anthropometric Dimensions for Male Agricultural Farm Workers in different Regions of India

Sandeep Singh Kharb[1], R.M. Belokar[2], Suman Kant[3]
[1, 2, 3]*Production and Industrial Engineering Department Punjab Engineering College (Deemed to be University),Chandigarh, 160012, India)*

Abstract: ***Various studies reported that agricultural sector is very hazardous in case of injuries and musculoskeletal disorders. A very large workforce is engaged in this sector hence the researchers should be focused in this sector for the improved machinery and equipment designs. A better compatibility of the worker with equipment enhances the safety and performance of the user. In this comparative study of various anthropometric traits of different regions of Indian agricultural population it is observed that north Indian males are largest (stature) out all regional population (1665 mm). Hand length found highest for central Indian workers (185 mm) and hand breadth is found highest for north Indian workers (100 mm).***
Key words: musculoskeletal disorders, Anthropometry, ergonomics, agricultural injuries

I. INTRODUCTION

In the daily tasks farm workers use a number of machine tools, manual tools and equipments. These tools must be compatible as per the physical traits of the user. Mismatches of tool dimension and user physical characteristics are the main concerned factors in reducing the worker's efficiency and can cause injuries and musculoskeletal disorders (MSDs) [Mandahawi et al., 2008]. So a number of researchers have reported the significance of relevancy of anthropometric data in tool and equipment design [Graves, 1992; Kar et al. 2003; Okunribido, 2000]. Anthropometric traits noticeably varies across gender, age, race, geographical locations, nutritional nature and types of work [Oduma et al., 2017]. It is reported and observed the presently agricultural mechanization needs a good knowledge of ergonomics for the better agricultural tools design with the specific concern of safety, comfort and efficiency of user using them [Yadav et al., 2000]. Different hand tools require different force and handling i.e some needs small force and some needs large handle forces so there is much complexity in ergonomic design of agricultural hand tools which require hand anthropometry [kar et al., 2003]. In general, hand tools are enormously heavy and tend to slip, hence difficult to handle and reduces efficiency of the user. Some users also try to personalize the tool design for their personal comfortability i.e. by reducing the diameter or varying the length of handle, removing protrusions or some sharp edges [Adegbite, 1994]. Till today, many manual tools are used in agricultural tasks in India i.e. from seedbed preparation to post harvest activities. Western nations have created the databases for anthropometric design references [Thompson, 1972; NASA, 1978; Syed, 1993]. Yet, such databases for Indian agricultural population is not available [Yadav et al., 2010; Vyavahare et al., 2016]. Various researchers from their studies and surveys has been reported that agricultural activities are highly prone to injuries and musculoskeletal disorders [Kharb et al., 2015]. Anthropometry plays a significant role in equipment design. Hence a critical study is done to compare the different anthropometric parameters of agricultural male population for different regions in India. In this present study, aim is to know the difference of mean of various anthropometric parameters so that the concept of tools design on the basis of anthropometry and its relevancy could be understood.

II. MATERIALS AND METHOD

A. Sampling for the survey

For the measurement (sample) workers selected were selected randomly and observed keenly to know that they must be free from any injury and musculoskeletal disorders. After knowing their health they were told the aim of research and measurement then after their consent they were considered as subject. All the selected subjects lie in the range of 18-60 years age group.

B. Apparatus used

The following equipments were used for data collection

©IJRASET: All Rights are Reserved

1) Anthropometer: to measure the various standing and sitting posture dimensions.
2) Wooden Cone: to measure the different grip diameters
3) Weighing scale: 100gm sensitivity, used to measure the body weight
4) Non-stretchable measuring tape: to measure wrist circumference
5) Vernier calliper: to measure different hand dimensions

C. Measurement Procedure

A team of well trained members went to the place of survey and took the sarpanch (head) of the village in confidence. Sarpanch of each surveyed village were informed about the aim of whole research then only with the help of sarpanch the workers were informed and called to come for subject selection *[Dewangan et al, 2010]*. During measurement subjects were asked to stand in the erect position with stretch shoulder in such a way that heel, buttock and head should touch the vertical plane *[NASA, 1978]*. Different breadth and height concern dimensions were measured using anthropopmeter. Vernier caliper was used to measure the different hand dimensions i.e. palm width, hand length, hand breadth etc. Measuring tape was used measure the girth of wrist. The whole procedure of measurement was repeated for three times to minimise the error in data collection.

D. Data Analysis

Mean and standard deviation was calculated from the collected data and presented in table1. Data of various regions of India is shown in table 1 i.e. North India(NI), North East India (NEI), East India (EI), Central India (CI), West India (WI) and South India (SI). 5th percentile and 95th percentile was calculated from the following formula:

$X = \mu + (z * \sigma)$ *[Yadav R., 1995]*

Where X is the ith percentile

μ = mean of the data

z = -1.645 for 5th percentile and +1.645 for 95th percentile

σ = standard deviation of the collected data for the specific region.

Calculated 5th and 95th percentile for the each specific region is shown in the table 2 and table 3 respectively. Calculated percentiles are used to design various farm tools and machinery anthropometrically *[Dixit et al., 2000]*.

III. RESULTS AND DISCUSSION

A. Results

Mean and standard deviation was analysed and compared for the different regions of India. Complete descriptive information is shown in table 1, 2 and 3. Machinery or farm manual tools are mainly designed for the 90 percentile i.e. (between 5th and 95th percentile). Hence mean, SD percentile are calculated and analysed to know the permissible limits of workers of the specific region. The height is highest for north Indian males found to be 1665 mm, smallest males are measured from north east Indian males i.e. 1618 mm.

B. Discussion

From table 1 it is observed that the highest stature is found for north Indian males and north Indian males are smallest out of all regions. North Indian males are larger by 2.9% than north east Indian males. Highest grip diameter (inside) for central Indian males (51 mm) is greater by 11.7% than lowest inside grip diameter (45 mm) Which is for north east Indian males.

Largest sitting height (845 mm) is found for eastern Indian males and smallest for south Indian males (781 mm), which is greater by 7.5%. Hand length for central Indian males is greater than north east Indian males by 5.9%. Highest hand breadth across thumb is observed for north Indian males (100 mm) and smallest is for east Indian males (95 mm), which is found smaller by 5% than north Indian males. From these results it can be suggested very well that from the above results some significant differences are observed in grip diameter which is critical dimension for fixing the handle diameters for the different agricultural tools. A significant difference is observed for hand breadth across thumb. Hand breadth is important parameter to decide the handle length for various hand tools like sickle.

IV. CONCLUSION

Different body dimensions are compared for various regions in India of male agricultural workers. North Indian males are largest in the other region population of Indian agricultural workers. Hand length of central Indian meals is found highest. Grip diameter is highest for the Central Indian males hence the diameter of handle of various hand tools i.e. khurpi, spade, sickle etc. will be the largest for these males. Highest hand breadth is found for north Indian males hence the larger handle length will be suitable for this population.

V. RECOMMENDATION

The use of ergonomics approach ie in design of different farm tool is not much in practice till these days. Hence the anthropometrical approach in tool design must be enhanced to improve the efficiency of farm workers and their safety (reduction of injuries and musculoskeletal disorders).
