Abstract: Utilization of industrial waste and agricultural waste products in the industry has been the focus of research for economic, environmental and technical reasons. Sugar Cane bagasse is a fibrous waste product of the sugar refining and causing serious environmental pollution which calls for urgent ways of handling the waste. In many situations, soils in natural state do not possess adequate geotechnical properties to be used as road service layers in rural areas. Bagasse ash can be utilized to stabilize the expansive soil. The aim of this research was to maintain environmental balance by avoiding the problem of ash disposal and to improve the subgrade characteristics of expansive soils. The soil taken for this study was classified as CH as per Indian Standard Classification System. Different dosages of bagasse ash i.e.2 %, 4%, 6% and 8% were used in this study to stabilize the expansive soil. The usage of this Bagasse ash material in road construction can prove efficient in increasing the strength of soil and in turn reducing the project cost. From the results it was observed that significant improvement of subgrade characteristics at addition of 4% bagasse ash with expansive soil.
Keywords: Bagasse ash, expansive soil, CBR, UCS, OMC and MDD

I. INTRODUCTION

Soil is a base of any structure, which actually supports it from beneath and distributes the load effectively. In many situations, soils in natural state do not possess adequate geotechnical properties to be used in many civil engineering works. Effective utilization of local weak soil by imparting additional strength using stabilization enables reduction in construction and improves performances for the projects related to civil engineering. Today, world is facing a serious problem in disposing the large quantity of agricultural waste like Bagasse, rice husk and groundnut shell etc. The disposal of agriculture waste without proper attention creates hazardous impact on environmental health. Sugarcane Bagasse Ash (SCBA) is the organic waste obtained from the burning of bagasse in sugar producing factories. Bagasse shows the presence of amorphous silica, which is an indication of pozzolanic properties, responsible for holding the soil grains together for better shear strength. The use of bagasse ash as stabilizing material for clayey soil can be checked under various tests such as standard proctor test, California bearing ratio and Unconfined Compressive Test (UCS) tests.

A. Scope of the Study

In remote rural villages, the development of road network is of vital importance in the socioeconomic development. Especially in rural villages having black cotton soil as subgrade, it is very difficult to lay the pavement. As the bagasse Ash is an industrial waste from cane mills, the optimum usage of this material in subgrade soil stabilization will bring down the construction cost of the pavements. In our study an attempt is made to stabilize black cotton soil with addition of bagasse ash. The strength parameters like OMC, MDD, CBR and UCS are determined to know the suitability of material.

II. MATERIALS

A. Black Cotton Soil: Black cotton soils are highly clayey soils, greyish to blackish in colour found in several states in India. The black cotton soil taken for the present study is collected from village Draksharama, District East Godavari from the depth of 0.3 to 0.4 m below the ground surface. Rich proportion of montmorillonite is found in Black cotton soil from mineralogical analysis. High percentage of montmorillonite renders high degree of expansiveness.
Sugar Cane Bagasse Ash: Generally Bagasse ash is the residue obtained from the incineration of bagasse in sugar producing factories. The Bagasse ash used in the study was collected from the field of village Guddippa of Visakhapatnam District. Initially the bagasse is collected from fields, dried and later set to fire. Finally Bagasse ash is obtained and is collected into bags. On visual inspection the Bagasse Ash appeared dark black color and comes in fibrous form. The obtained bagasse is then sieved through 4.25 microns.

III. METHODOLOGY
The following gives the list of main tests performed in order to study and determine the subgrade characteristics of black cotton soil and soil + bagasse ash.

A. Compaction
Test was done in accordance to Indian standards code of practice (IS 2720 PART-7, 1980). Physical method of testing was used for this test.

B. CBR Test
Test was done in accordance to Indian standards code of practice (IS 2720 PART-16, 1987) for laboratory testing.
C. UCS Test
Test was done in accordance to Indian standards code of practice (IS 2720 PART-10, 1991) for laboratory testing.

IV. RESULTS AND DISCUSSIONS

The following results were obtained in standard proctor test and the following table represents the variation of moisture content and MDD with different proportions of bagasse ash.

Table 2. Variation of OMC and MDD with Bagasse ash

The addition of bagasse ash by weight (2%, 4%, 6%, 8%) to the soil sample caused decrease in OMC from 16.27% to 15.68% for 2% to 4% of bagasse ash and later it was observed that there is increase in OMC with increases in content of bagasse ash whereas decrease in MDD value for the same content of bagasse ash.

The California Bearing Ratio test of soil is conducted with various percentages of sugarcane bagasse ash on black cotton soil. In case of variation of unit load with respect to penetration of soil with same percentages of bagasse ash the obtained curves are shown below:

Fig. 3. Variation of Unit load against penetration
The addition of bagasse ash up to weight of (0%, 2%, 4%, 6%, 8%) to the soil samples caused an increase in CBR value at the rate of 3.4%, 4.13%, 5.38% up to 4% and later there is decrease in CBR value at the rate of 3.31% and 2.94% respectively. The following chart clearly indicates the variation.

![Variation of CBR with Bagasse ash](image1)

**Fig.4. Variation of CBR with Bagasse ash.**

The unconfined compressions test were conducted with various percentages of sugarcane bagasse ash on black cotton soil and the following figure represents the variation of unconfined compression strength with percentage of bagasse ash. The stress versus strain behaviour is also shown in the same figure with various percentages of bagasse ash.

![Stress stain response of soil with various % of bagasse ash](image2)

**Fig.5. Stress stain response of soil with various % of bagasse ash.**

The addition of bagasse ash up to weight of (0%, 2%, 4%, 6%, 8%) to the soil samples caused an increase in UCS value at the rate of 0.41, 0.58, 1.066 kg/cm² up to 4% and later there is decrease in UCS value at the rate of 0.571 and 0.53 kg/cm² respectively. The following chart clearly indicates the variation.
V. CONCLUSIONS

From the values noted above, there was noticeable increase in California bearing ratio of soil when optimum ratio of bagasse ash is added. And to the same ratio, by observing the stress – strain graph drawn for unconfined compressive strength can be valid and ration of bagasse ash can be used. Hence in conclusion, bagasse ash can be used in stabilization of black cotton soil and the optimum content from our study was noticed as 4% by weight.
