# Design of Improved Array Multiplier by Carry Select Logic

Silpa Raj P<sup>1</sup>, Punitha V<sup>2</sup>

Department of Electronics & Communication Engineering, AWH Engineering College, Kozhikode, India

**Abstract**— Multiplier is such an important element from the point of power consumption and speed of operation in the system. Multiplication using deletion scheme provides an efficient method for reducing the power and area as compared to that of full width multiplier. This paper is about the implementation of array multiplier using carry select adder for improving speed of operation of the multiplier. Array multipliers with deletion scheme offer significant improvement in area, delay & power. The proposed method finally reduces a set of full adders by carry select adder. While implementing this proposed method experimentally, delay in operation can be saved.

**Keywords**—Multiplier; Array; carry select adder; carry propagation adder; Resister Transistor Level.

## I. INTRODUCTION

Multipliers play important role in today’s digital signal processing and various other applications. With advances in technology, many researchers have tried and are trying to design multipliers with offer either of the following design targets of high speed, low power consumption, regularity of layout and hence less area or even combination of them in one multiplier thus making them suitable for various high speed, low power and compact VLSI implementation. Multiplication involves three basic operations a) generation of partial product b) accumulation of partial products c) and calculates their sum. Multiplication algorithms are of two, serial and parallel. Serial multiplication algorithms use sequential circuits with feedback. Parallel multiplication algorithm often uses combinational circuits and do not contain feedback structure.

## II. ARRAY MULTIPLIERS

Array multiplier is well known due to its regular structure. Multiplier circuit is based on add and shift algorithm[1],[4]. Each partial product is generated by the multiplication of the multiplicand with each multiplier bit. The partial products are shifted according to their bit orders and then added. The addition can be performed with normal carry propagation adder. N-1 adders are required where N is the multiplier length. Fig.1 shows the basic operation of the 8 x 8 array multiplier. In this method product is generated irrespective of the multiplier bit value and become area and delay of operation increases[5].

### III. ARRAY MULTIPLIER WITH DELETION SCHEME

The proposed method involves deletion, which is done at the stage of partial product generation section. whenever a value of multiplier is '0', the multiplier doesn't added to the accumulator. Only bit level shifting was done at this stage. In other words the partial product bits are deleted when the multiplier bit is '0'. If the multiplier bit is '1', then the multiplicand is added to the accumulator and finally the partial products is carried out by the carry propagation adder

#### A. Shift and add multiplier

The general architecture of the shift and add multiplier for a 8-bit multiplication is shown in the figure below[6]. Depending on the value of multiplier LSB bit, a value of the multiplicand is added and accumulator. At each clock cycle the multiplier is shifted one bit to the left and its bit value is checked either it is '0' or '1'. When the bit value of multiplier is '0', the concerned partial product is not generated, only a bit level shift operation is performed in the accumulator register. If the bit value is '1', then the multiplicand is added to the accumulator and one significant bit level is shifted to the left for receiving the next partial product. After all the multiplier bits have been tested, the partial product is added and the resultant product is stored in the accumulator. The accumulator is  $2N (M+N)$  in size and initially the  $N$ , LSBs contains the Multiplier. The delay is  $N$  cycles maximum.

**IV. ARRAY MULTIPLIER WITH CARRY SELECT ADDER**

The project is about the implementation of array multiplier with deletion scheme and carry select adder for improving speed of operation of the multiplier. Array multiplier with deletion scheme offers significant improvement in area, delay & power. The combination of these two will get the preferred result. In the proposed method, the carry select adder circuit is employed instead of carry propagation adder circuit logic and thereby a set of adders could be replaced by one carry select adder. While implementing this proposed method experimentally, time of operation and area can saved.

**A. Multiplier Using Carry Select Adder**

Carry Select Adder (CSLA) is one of the fastest adders used in many data-processing processors to perform fast arithmetic functions[2][3]. From the structure of the CSLA, it is clear that there is scope for reducing the delay in the CSLA. The CSLA is used in many computational systems to alleviate the problem of carry propagation delay by independently generating multiple carries and then select a carry to generate the sum[7][8]. In this project carry select adder is used to reduce the delay and area. Figure shows the block diagram of the multiplier by using carry select adder. Here the main difference is the carry propagation adder is replaced by carry select adder. n x n bits multiplier computes the 2n bits output as a weighted sum of partial products. For the addition of partial products carry select adder is used it will reduce the time of operation.

**B. Block Details**

The design was implemented using a mixture of both structural design and RTL level design. In each case the choice of style is described. The block diagram showed in Figure details the breakdown of VHDL modules.

1) *Controller design:* The Controller is the control unit of the multiplier. It receives a START signal and consequently commands all other modules until the result is obtained and it output a STOP signal. Controller commands the loading,

## International Journal for Research in Applied Science & Engineering Technology (IJRASET)

shifting and counting operations

- 2) *Multiplicand block design* : The Multiplicand block is composed of 8 D Flip-Flop blocks, which store A byte for processing during the complete multiplication cycle. The register is loaded with the LOAD command signal from the Controller.
- 3) *Multiplier/Result block design* : The Multiplier/Result block stores the multiplier (.B. byte) as well as the accumulated output of the adder. It allows the register to be logically shifted right and provides one of the adder's inputs. The Multiplier/Result block consists of a 17-bit shift register and a multiplexer in order to provide this functionality.
- 4) *Adder design* : The adder design is the most influential part of the multiplier in terms of the area and speed achievable. This is due to the large iterations of additions performed in the multiplication cycle
- 5) *Multiplier design* : The complete multiplier is simply a top-level module which instantiates all the lower level functional modules described in the previous sections.
- 6) *Carry select adder* : The concept of the carry-select adder is to compute alternative results in parallel and subsequently selecting the correct result with single or multiple stage hierarchical techniques. In order to enhance its speed performance, the carry-select adder increases its area requirements. In carry-select adders both sum and carry bits are calculated for the two alternatives: input carry "0" and "1" Once the carry-in is delivered, the correct computation is chosen(using a MUX) to produce the desired output. Therefore instead of waiting for the carry-in to calculate the sum, the sum is correctly output as soon as the carry-in gets there. The time taken to compute the sum is then avoided which results in a good improvement in speed.

### V. SOFTWARE USED

The project is carried out in VHDL Language. And it was simulated in XILINX ISE 12.2 (Integrated Software Environment) design suit. Xilinx ISE is a software tool produced by Xilinx for synthesis and analysis of HDL designs, enabling the developer to synthesize ("compile") their designs, perform timing analysis, examine RTL diagrams, simulate a design's reaction to different stimuli, and configure the target device with the programmer.

### VI. EXPERIMENTAL RESULT

Table 1.Experimental Result

BIT LENGTH 8BIT	DELAY (ns)
ARRAY MUL WITHOUT DELECTION SCHEME	220.5
ARRAY MUL USING CPA	184.3
ARRAY MUL USING CSLA	145.7

### VII. CONCLUSION

advantage is delay increases slowly as the input bit increases. In this paper deletion is limited to partial product generation area so the result becomes absolutely free of error.
