**Abstract:** The objective of this paper is to estimate the parameters of Lomax distribution with shape parameter( $\alpha$ ) and scale parameter( $\lambda$ ). In this heuristic algorithm, the Median Rank regression method is used to Estimates the parameters of Lomax Distribution. We also computed Average Estimate (AE), Variance (VAR), Mean Absolute Deviation (MAD), Mean Square Error (MSE), Relative Error (RE) and Relative Absolute Bias (RAB) for both the parameters under grouped sample based on 1000 simulations to assess the performance of the estimators.

**Keywords:** Lomax Parameters, Grouped sample, Median Rank regression method, simulation.

## I. INTRODUCTION

The Lomax distribution, conditionally also called the Pareto Type II distribution, is a heavy-tail probability distribution used in business, economics, actuarial science, queueing theory and Internet traffic modeling. It is named after K. S. Lomax. It is essentially a Pareto distribution that has been shifted so that its support begins at zero.

The Lomax distribution, also called “Pareto type II” distribution is a particular case of the generalized Pareto distribution (GPD). The Lomax distribution has been used in the literature in a number of ways. For example, it has been extensively used for reliability modelling and life testing; see, for example, Balkema and de Haan [1]. It also has been used as an alternative to the exponential distribution when the data are heavy tailed; see Bryson [2]. Ahsanullah [3] studied the record values of Lomax distribution. Balakrishnan and Ahsanullah [4] introduced some recurrence relations between the moments of record values from Lomax distribution. The order statistics from nonidentical right-truncated Lomax random variables have been studied by Childs et al. [5]. Also, the Lomax model has been studied, from a Bayesian point of view, by many authors; see, for example, Arnold et al. [6] and El-Din et al. [7]. Howlader and Hossain [8] presented Bayesian estimation of the survival function of the Lomax distribution. Ghitany et al. [9] considered Marshall-Olkin approach and extended Lomax distribution. Cramer and Schmiedt [10] considered progressively type-II censored competing risks data from Lomax distribution. The Lomax distribution has applications in economics, actuarial modelling, queueing problems and biological sciences; for details, we refer to Johnson et al. [11]. In this paper, we develop a practical approach for estimating the shape( $\alpha$ ) and scale ( $\lambda$ ) parameters of the LD using the median rank regression method. We therefore employ these estimates as the median ranking method. We present the observations and the conclusions based on the simulation results.

## II. MEDIAN RANK REGRESSION METHOD TO ESTIMATE THE LOMAX DISTRIBUTION PARAMETERS:

Let  $x_1, x_2, \dots, x_n$  be a random sample of size  $n$  from LD( $\alpha, \lambda$ ), its Probability Density Function (PDF) and cumulative distribution function(CDF) are given by

$$f(x) = \frac{\alpha}{\lambda} \left[ 1 + \frac{x}{\lambda} \right]^{-(\alpha+1)}; x \geq 0, \alpha > 0, \lambda > 0 \quad (2.1)$$

$\alpha$ =shape parameter

$\lambda$ =scale parameter

$$\text{CDF } F(X) = 1 - \left( 1 + \frac{x}{\lambda} \right)^{-\alpha} \quad (2.2)$$

$$1-F(X) = \left( 1 + \frac{x}{\lambda} \right)^{-\alpha} \quad (2.3)$$

Applying log on both sides to (1.2.3)

$$\text{Log}(1-F(X)) = -\alpha \log\left(1 + \frac{x}{\lambda}\right) \quad (2.4)$$

$$\text{Log}(1-F(X)) = -\alpha \log x + \alpha \log \lambda \quad (2.5)$$

$$\text{Let us consider } U = \log(1-F(X)), V = \log x, B = -\alpha, A = \alpha \log \lambda \quad (2.6)$$

F(x) is obtained by using the median rank method (also known as Benard's approximation), which is a good estimate of the median rank estimate. Benard's median rank was used because it showed the best performance and was the most used rank for prediction (F(x)). The procedure for ranking the complete data is as follows:

- 1) List the time to failure data from small to large.
- 2) Use Benard's formula to assign median ranks to each failure.
- 3) Estimate the  $\alpha$  and  $\lambda$  by Equations (1.2.6)

$$4) F(x) = \frac{i - 0.3}{N + 0.4}, i = 1, 2, \dots, N.$$

Where  $i \rightarrow$  The ranked position of data point and

$N \rightarrow$  The total number of units in the sample

$$\tilde{A} = \frac{\left(\sum_{i=1}^n v_i^2\right)\left(\sum_{i=1}^n u_i\right) - \left(\sum_{i=1}^n v_i\right)\left(\sum_{i=1}^n v_i u_i\right)}{\left(n \sum_{i=1}^n v_i^2\right) - \left(\sum_{i=1}^n v_i\right)^2} \quad (2.7)$$

$$\tilde{B} = \frac{n\left(\sum_{i=1}^n v_i u_i\right) - \left(\sum_{i=1}^n v_i\right)\left(\sum_{i=1}^n u_i\right)}{\left(n \sum_{i=1}^n v_i^2\right) - \left(\sum_{i=1}^n v_i\right)^2} \quad (2.8)$$

F(X) is estimated from the median ranks. Once  $\tilde{A}$  and  $\tilde{B}$  obtained, the values of  $\hat{\alpha}$  and  $\hat{\lambda}$  can easily be obtained.

#### A. Simulation Study

In order to obtain the median ranks method estimators of shape( $\alpha$ ) and Scale ( $\lambda$ ) is used to obtain estimators and to study their predictive properties by Average Estimate (AE), Variance (VAR), Mean Square Error (MSE), Relative Absolute Bias (RAB) and Relative Error (RE). If  $\hat{\psi}_{lm}$  is Median Ranks Method estimate of  $\hat{\psi}_m$ ,  $m=1, 2$  where  $\psi_m$  is a general notation that can be replaced by  $\psi_{m1} = \lambda, \psi_{m2} = \alpha$  based on sample  $l$ , ( $l=1, 2, \dots, r$ ), then the Average Estimate (AE), Variance (VAR), Mean Absolute Deviation (MAD), Mean Square Error (MSE) and Relative Absolute Bias (RAB) and Relative Error (RE) are given respectively by

$$\text{Average Estimate } (\hat{\psi}_m) = \frac{\sum_{l=1}^r \hat{\psi}_{lm}}{r}$$

$$\text{Variance } (\hat{\psi}_m) = \frac{\sum_{l=1}^r (\hat{\psi}_{lm} - \overline{\hat{\psi}_{lm}})^2}{r}$$

$$\text{Mean Absolute Deviation} = \frac{\sum_{l=1}^r \text{Med}(|\hat{\psi}_{lm} - \overline{\hat{\psi}_{lm}}|)}{r}$$

$$\text{Mean Square Error } (\hat{\psi}_m) = \frac{\sum_{l=1}^r (\hat{\psi}_{lm} - \psi_m)^2}{r}$$

$$\text{Relative Absolute Bias } (\hat{\psi}_m) = \frac{\sum_{l=1}^r |\hat{\psi}_{lm} - \psi_m|}{r \psi_m}$$

$$\text{Relative Error } (\hat{\psi}_m) = \frac{1}{r} \left( \frac{\sum_{l=1}^r \text{MSE} \sqrt{(\hat{\psi}_{lm})^2}}{\psi_m} \right)^2$$

### B. Simulated Data Sets

We evaluate the performance of the Median Ranks Regression (MRR) method for estimating the LD ( $\alpha, \lambda$ ) and Newton-Raphson simulation for two parameter combinations, and the process is repeated 10,000 times for different sample sizes  $n = 50$  (50) 500 considered.

MRR and their Average Estimate (AE), Variance (VAR), Mean Absolute Deviation (MAD), Mean Square Error (MSE), Relative Absolute Bias (RAB), and Relative Error (RE) of the median rank method to estimators of scale and Location parameters. Population parameters shape=1 and Scale =1

We evaluate the performance of the Median Ranks Regression (MRR) method for estimating the Rayleigh distribution with shape ( $\alpha$ ) and Scale ( $\lambda$ ) parameters, Newton-Raphson simulation for a two parameter combinations was done and the process is repeated 10,000 times for different sample sizes  $n=50(50)500$ .

The MRR and their Average Estimate (AE), Variance (VAR), Mean Absolute Deviation (MAD), Mean Square Error (MSE), Relative Absolute Bias (RAB) and 15 Relative Error (RE) of Median Ranks method for the estimators of location and scale parameters of the Rayleigh distribution are evaluated. The simulated results were presented in Table-1.2 for the values of the parameters Location=1 and Scale =0.5.

### III. OBSERVATIONS AND CONCLUSIONS FROM SIMULATION RESULTS

#### A. Observations

- 1) The Average Estimate (AE), Variance (VAR), Standard deviation (STD), Mean Absolute Deviation (MAD), Mean Square Error (MSE) and Relative Absolute Bias (RAB), Relative Error(RE) are independent of true values of the parameters of shape ( $\alpha$ ) and Scale ( $\lambda$ ).
- 2) Average Estimate (AE) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are increasing when we take large number of observations.
- 3) Average Estimate (AE) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when we take small number of observations.
- 4) Variance (VAR) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when sample size (n) is increasing.
- 5) Mean Absolute Deviation (MAD) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when sample size (n) is increasing in most of the situations.
- 6) Mean Square Error (MSE) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when sample size (n) is increasing.
- 7) Relative Absolute Bias (RAB) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when sample size (n) is increasing.
- 8) Relative Error (RE) of shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) by Median Ranks Method are decreasing when sample size (n) is increasing.
- 9) When we take least values the results of AE, VAR, STD, MAD, MSE, RAB, RE are very low when comparing to highest values result.

#### B. Remarks

In this Median Ranks Regression Estimation method the parameters in Lomax Distribution it is observed that

- 1) Variances of the shape parameter ( $\alpha$ ) and Scale parameter ( $\lambda$ ) are decreasing when Sample size (n) increases.
- 2) When compared with small sample sizes, the shape parameter ( $\alpha$ ) and Scale Parameter ( $\lambda$ ) estimators in large sample are more efficient.
