Biological Study and Fish Culture of Marpha Pond District Anuppur, Madhya Pradesh

Amar Bahadur Singh

(Scientific Officer), Biology/Serology- Section, State Forensic Science Laboratory Civil Line
University Road Sagar Madhya Pradesh - 470001

Abstract: *The present paper deals with the seasonal variations in some important Physico-chemical parameters and Biological analysis of the fish Pond of Anuppur District of Madhya Pradesh using selected standard classical methods with an objective to investigate present condition for its better utilization. The data collected in various seasons (summer, winter and rainy) study revealed that those analyzed parameters were within permissible limit for fish culture and the stocking should be done as per the productivity of the water. There is good scope to increase the production by increasing the carrying capacity of the water bodies.*

Keywords: *Fish Culture, Anuppur, Physico-chemical analysis.*

I. INTRODUCTION

Physico-chemical analysis of fresh water resources are scattered throughout the district and are under fish culture on extensive or semi intensive way giving some income to the growers. The number of dams, reservoirs, tanks, etc. has significantly increased in last few years. The development of fisheries in these fresh water resources is the present need using scientific techniques. The abiotic and biotic factors of the water influence the quality and quantity of aquatic life surviving there. The role of water in nature is unique not only for human; but, also for the numerous organisms living in the water. The physical and chemical properties of fresh water bodies are characterized by the climatic, geochemical, geo morphological and pollution condition. In order to utilize fresh water bodies successfully for fish production, it is very important to study the Physico-Chemical factors influencing the biological productivity in the water bodies. The quality of aquatic life surviving in the pond is totally dependent on the water quality of the pond. In the recent years several studies have been made in this field but not much information is available on Physico-Chemical and Biological parameters of the present water bodies. Hence the present work is an attempt to study the detailed information on some important Physico-chemical and Biological parameters of the fish pond so that necessary measures could be suggested for the best fish culture practices in the District Anuppur Madhya Pradesh.

II. MATERIALS AND METHODS

The study site lies between 23°6'0" N Latitude and 81°41'1" E Longitude. Anuppur district situated in the north eastern part of Madhya Pradesh. This District came into existence on 15th August 2003 by re-organising Shahdol District. Anuppur District has total area of 3701 Sq.km., extends 80 km from east to west and 70 km from north to south. District Anuppur is surrounded by Korias District (C.G.) in east, Shahdol & Umaria district in west. Shahdol district in north and Dindori (M.P.) Bilaspur (C.G.) in the south. The Marpha pond is perennial one. The area of pond is nearly 17 Hactare. It is situated inside of the city. According to local residents it was digged by Pandavas but some people also says that this pond had been made by the authority of municipality before 100 years ago. During the time of Hindu festivals all the statues of Devi and Deotas are disposed in to the pond, so due to these activities water is becomes polluted. The fisheries department also culture the fishes. Hence this pond has been under taken during present study for physicochemical analysis of water along with fish culture. (Figure 1).

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

Figure 1. Location Map of Study area District Anuppur in Marpha Pond

The fish pond has been selected on random basis for the study which are under fish culture practices. Monthly sampling was done from June 2014 to May 2015 in all the ponds for finding out the various abiotic (Temperature, Transparency, pH, Dissolve Oxygen, free CO₂, total Alkalinity, Biological Oxygen Demand (BOD) and biotic parameters. The Physico-chemical analysis of the water samples were done according to APHA (1998).

The estimation of planktonic population, samples were collected with the aid of a mug of one litre capacity. 50 litres of water was collected through the Plankton net made of bolting silk no. 25 (0.064 mm mesh size) to obtain the plankton sample and was preserved by adding 24% of formalin for further study. The data collected was grouped in three categories i.e. summer (February-May), Rainy (June-September) and winter (October-January) for comparison of seasonal variations. Ecosystem. (Dwivedi and Pandey 2002). In the present study the water temperature range.

13.0 °C to 31.7 °C. It was maximum during summer comparatively less during monsoon and minimum during winter. Kannan and Job (1980) also found similar results as observed in the present study The temperature ranges indicate the suitability for fish culture (Jhingran, 1982) even though the minimum temperature recorded in the month of December (13 °C) is also within the permissible limit of the fish culture.

III. RESULTS AND DISCUSSION

This fish Pond is perennial, non-drainable, utilized for bathing, washing clothes and utensils. The physicochemical analysis made in various seasons in this pond have been shown in the **Table 1**.

Table 1: Physico-chemical and Biological Parameters of Marpha Pond, District Anuppur, Madhya Pradesh.

S.No.	Parameters	Summer	Rainy	Winter
1.	Temperature (°C)	31.55	29.68	23.90
2.	pH	7.35	7.42	7.38
3.	Transparency (cm.)	31.93	26.10	34.85
4.	Dissolve Oxygen (ppm.)	5.68	6.38	7.78
5.	Carbon Dioxide (ppm.)	5.34	5.08	4.39
6.	Alkalinity (ppm.)	137.3	95.0	147.3
7.	Hardness (ppm.)	185.3	102.3	189.3
8.	Electrical Conductivity	308.0	190.0	253.8
9.	Total Dissolve Solids (ppm)	521.0	564.5	467.5
10.	Biological Oxygen Demand (at 25°C)	2.825	2.350	2.300
11.	Plankton (ml.)	0.1	0.2	0.3

Graph 1. : Physico-chemical and Biological Parameters of Marpha Pond, District Anuppur, Madhya Pradesh.

IV. TEMPERATURE

Temperature plays an important role in aquatic environment and considered as an important factor in controlling the functioning of aquatic

V. PH

pH is a limiting factor and works as an index of general environmental condition. The pH value of the pond showed alkaline trend. The maximum pH value were in the month of April i.e. 7.42 and minimum in the month of October i.e. 7.35. It is evident from the data that the pH declines during the rainy season and increases during summer. pH status in the aquatic environment on important chemical parameters which predicts about the suitability for the fish culture. The alkaline pH is suitable for fish culture (Jhingran, 1982). The pH was more in where there is washing of the cloths and less where the cattle waste are disposed, but overall the pH was same and was little alkaline which is most suitable for the fish culture.

VI. TRANSPARENCY

Water transparency is an important factor that controls the energy relationship at different trophic levels. The results of transparency ranged between 34.85 cm to 26.10 cm, during the study period. It was low during the summer and higher during the winter season. The transparency was lower in the summer season due to high planktonic population, while it was low in the rainy season because of increase in the suspended matter brought in through surface run off. The maximum transparency was recorded in winter season attributed to the sedimentation of suspended matter (Chaurasia and Adoni, 1985). Transparency plays vital role in nutrient transformation and also gives an indication of productivity of the water. The Availability of the plankton influences the transparency of the water. The water was more transparent in the rainy season in comparison to the winter and summer season may be due to poor diluted plankton in the rainy season.

VII. DISSOLVE OXYGEN

Oxygen content is important for direct needs of many organisms and affects the solubility of many nutrients and therefore the periodicity of aquatic ecosystem (Wetzel, 1983), Jhingran (1982) stated that the oxygen contents in tropical water would be low considering their high temperature. The results of the present study showed that highest peak value of dissolved oxygen was recorded during the winter season i.e. 7.78 ppm least in rainy season i.e. 5.68 ppm. The minimum dissolved oxygen has been noticed in summer may be due to excessive temperature which reduces the solubility of oxygen. The higher temperature also increases the decomposition rate and the lowers the oxygen Results of the present study are similar to other workers (Prasad *et al.*, 1985).

VIII. CARBON DIOXIDE

The normal water receive carbon dioxide from various sources i.e. (1) The atmosphere. (2) Respiration of plants and animals. (3)

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

Bacterial decomposition of organic matter. (4) Inflowing ground water. The carbon dioxide bears a correlation with pH. The increase in carbon dioxide decreases pH (acidic). The CO₂ varied from 5.34 to 4.39 ppm. Maximum free CO₂ in was observed in summer season and minimum in the rainy season. The free carbon dioxide concentration depends on the respiration of organism (plants and animals) and photosynthesis rate. In case of more photosynthesis more carbon dioxide will be utilized.

IX. ALKALINITY

Alkalinity is a function of bicarbonate and carbonates. These salts get hydrolyzed in solution and produced hydroxyl ion. It is also used as a measure of productivity of water (Jhingran, 1982; Hulyal and Kaliwal, 2011). Natural water bodies in tropics usually show wide range of fluctuations in their total alkalinity value depending upon the geography and season. In the present study the total alkalinity ranged between 147.3 ppm to 95.0 ppm. It is gradually decreased from July to September and then increased in the month of October. Seasonally highest value was recorded during rainy and lowest during the summer season. Increases in total alkalinity during rainy season were due to input of water and dissolution of calcium carbonate ion in the water column (Padma and Periakali, 1999). The degradation of plants and other organism and organic waste might also be one of the reason for the increase in carbonate and bicarbonate thereby the alkalinity (Jain *et al.* 1997).

X. HARDNESS

Hardness in water is due to salts of Ca⁺⁺ and Mg⁺⁺ mainly in the form of carbonates and sulphates. In the present study the total hardness of water ranged from 140228 ppm seasonally, highest value was recorded during summer and lowest during the rainy season. Similar observations were found by various workers (Kumar, 1995; Naik and Purohit, 1996). Hulyal and Kaliwal (2011) found that higher value in summer and lower in winter season. They attributed is to decreases in water volume and increases in rate of evaporation at high temperature. The water can be categorized according to degree of hardness as soft (0-75 mg l⁻¹) moderately (75-150 mg l⁻¹) hard, (189.3-102.3 mg l⁻¹) and above 300 mg l⁻¹ as very hard. On the basis of the observation, the water of the present pond appears to be hard.

XI. ELECTRICAL CONDUCTIVITY

Electrical conductivity of the water depends on the nature and concentration of salts in high ionic concentration, pollution status, trophic levels, some domestic effluents and other organic matter in water (Ahluwalia, 1999). The range of electrical conductivity in the present study was between 308 -190. The values of electrical conductivity showed marked seasonal variation being maximum during rainy and minimum during winter season. Similar results were observed by various workers (Hulyal and Kaliwal, 2011; Ramulu and Benarjee, 2013).

XII. TOTAL DISSOLVE SOLIDS

Water is a universal solvent and have a large number of salts dissolved in it which largely govern the physico-chemical properties. The maximum value of total dissolved solids was recorded in rainy season 564.5 ppm and minimum were recorded in winter season 467.5 ppm. The high value of TDS during rainy may be due to addition of domestic waste water, garbage and sewage etc. in the natural surface water body.

XIII. BIOLOGICAL OXYGEN DEMAND

BOD is dissolved oxygen required by microorganism for aerobic decomposition of organic matter present in water. BOD has considered as an important parameter in aquatic ecosystem to establish the status of pollution. The observation of present study showed that highest value of BOD value during rainy season 2.825 ppm and lowers during winter season 2.300 ppm. Seasonally, the BOD was highest during late summer /early rainy season. High BOD during late summer / early rainy season may be due to the presence of several microbes in water bodies which accelerate their metabolic activities with the increase in concentration of organic matter in the form of municipal and domestic waste pouring into the pond with run off. It is also stated that the higher values of BOD during rainy was also due to input of organic wastes and enhanced bacterial activity. High temperatures do play an important role by increasing rate of oxidation. The BOD of unpolluted water is less than 1.00 ppm moderately polluted water 2.00-9.00 ppm while heavily polluted water have BOD more than 10.00 ppm. The BOD in different season in the present study indicates pond as moderately polluted.

XIV. PLANKTON

The plankton concentration varied from 0.1 to 0.3 ml/25 l of water. It was more in winter season and low in summer season. The

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

concentration is low for commercial fish culture (Jhingran, 1982)

XV. CONCLUSION

Present observation of the different parameters revealed that the physico-chemical and biological parameters are within the permissible limit for fish culture except the concentration of plankton. It may be due to over stocking or more organisms feeding on plankton. It may be recommended that the stocking of the pond should be done on the basis of the natural productivity of the water or supplementary feeding (if possible) to have better production. Our study gives emphasis of involvement and educate the local people for safe disposal of effluents is essential. Our analysis for BOD of the ponds falls under moderately polluted category which should be solved in future for better productivity.

XVI. ACKNOWLEDGEMENT

Author is thankful to Dr. Mohammad Husain, Principal Govt. Nehru P.G. College Burhar District Shahdol, (M.P.) and Dr. A.A. Khan Retd. Professor and Head Dept. of Botany Govt. Girls P.G. College Rewa (M.P.) for valuable suggestion and carried out this work.
