Flow-Based Network Traffic Classification Using Clustering Technique with MLA Approach

Triveni Pujari[1], Nalinakshi B. G[2], Dr.D Jayaramaiah[3]
[1, 2,3]*Dept. Of ISE, The Oxford College of Engineering, Bengaluru-68, India.*

Abstract*: *Network traffic classification is the process of categorizing network traffic according to various parameters into a number of traffic classes and it is necessary to maintain smooth operation of the network. There are so many methods to classify the network traffic. The proposed methods use machine learning algorithm i.e (MLA) approach. In MLA approach, a system learns from empirical data to automatically associate objects with corresponding classes. There are two types of MLAs one is supervised and the other is unsupervised. Supervised methods consist of labeled data to classify any flows into pre-defined traffic classes, but they cannot deal with unknown flows hence we use unsupervised clustering method along with supervised approach to cluster and classify both known and unknown flows. We applied hybridization of both supervised and unsupervised algorithm to achieve better accuracy. A number of real world traffic traces have been used to show the assessment of traffic classes and to test the proposed approach. The experimental results indicate that by incorporating special features of data packets in the course of clustering, enhances accuracy and cluster purity with significant improvement.

Keyword : Traffic classification, unsupervised machine learning, clustering, iterative approach, Wireshark, Tranalyzer

I. INTRODUCTION

Traffic classification (i.e., associating traffic flows with their source applications) has attracted increasing research efforts in the last decade. The explosion of this research area started when the traditional approach of relying on transport-level protocol ports became unreliable, mainly because of the increasing variety and complexity of modern Internet traffic and application-level protocols. The reason for the growth in Internet traffic data is due to the bandwidth-hungry applications like File Transfer applications, Video Streaming, Social Media Network (Facebook, Twitter etc.), Mobile applications, E-commerce websites, Stock Exchange data and much more. As the traffic data increases it is necessary to analyse, measure, and classify it as ISP and Network Administrators need it for various perspectives like network planning, traffic shaping, billing and to extract useful information. This task needs to be performed with various tools available in market (Ex: tcpdump, Wireshark etc.)These tools capture the network traffic and store it onto a local server for further processing.

Network traffic classification is the process of classifying traffic based on their applications. Nowadays due to the growth of internet users and bandwidth hungry applications the traffic generated in the network is very high. There are many methods for classification of network traffic, they all try to classify the network traffic accurately but classification accuracy is less. From the very beginning of the internet, since there were not so many users and therefore, not so many applications, traffic classification was done using the well-known ports defined by IANA [16]. Classification based on well-known TCP or UDP ports is becoming increasingly less effective, due to the numbers of networked applications are port-agile (allocating dynamic ports as needed), end users are deliberately using non-standard ports to hide their traffic, and use of Network Address Port Translation (NAPT) is widespread (for example a large amount of peer-to-peer file sharing traffic is using non-default ports).

Payload-based classification relies on some knowledge about the payload formats for every application of interest: protocol decoding requires knowing and decoding the payload format while signature matching relies on knowledge of at least some characteristic patterns in the payload. This approach is limited by the fact that classification rules must be updated whenever an application implements even a trivial protocol change, and privacy laws and encryption can effectively make the payload inaccessible.

To overcome the above issues we are using machine learning approach to classify the traffic. In our work we are implementing an unsupervised clustering approach to classify the network traffic because unsupervised is that of trying to find hidden structure in unlabelled dataset. Clustering analysis is one of the unsupervised approaches and it is the process of making set objects in such a

©IJRASET (UGC Approved Journal): All Rights are Reserved

way that objects in the same group are more similar to each other than to those in other group. In our work we proposed automatic-learning algorithm using clustering techniques. Each flow indicates the packet size, packet length, inter-arrival time etc. So we can easily get the flow information for classification because these features are known to carry valuable information about the protocol and the applications that generated the flow.

II. LITERATURE SURVEY

The author in paper [1] proposes internet traffic classification using supervised learning algorithm and makes comparative analysis between machine learning algorithms. The main focus in this paper is the selection of feature sets. Hence it is concluded that the supervised decision tree based algorithms provide better performance and accuracy than the other supervised algorithms like KNN, naive Bayes etc. But accuracy of these decision tree based algorithms is poor while applying them for classifying P2P applications.

According to author in paper [2] Self-learning classifier is an unsupervised clustering algorithm with an adaptive seeding approach. It helps to automatically identify the classes of traffic being checked and labelled. This algorithm automatically groups flows into pure clusters using statistical features. Hence this paper acts as a base to our project as it summarises the state of the art of cluster analysis and here the main target of the classification is flows. Each flow is characterised by simple metrics, like segment size and inter arrival times.

According to Zhang, jun, et al. in paper [3] the classification of network traffic was done by correlation information. The traditional methods suffer from a number of practical problems, such as dynamic ports and encrypted applications so machine learning techniques have been focused to classify the traffic. Machine learning can automatically search for and describe useful structural patterns in a supplied traffic dataset. The correlation analysis can improve the classification accuracy and system flexibility. The proposed approaches can be used for recognising unknown application from captured network traffic and semi supervised data mining for processing network packets.

We selected paper [4] to understand the self-adaptive approach for network traffic classification. The author presented a novel, fully automated Packet Payload Content (PPC) Based network traffic classification system. System learns new application in the network where classification is desired. Hence the proposed algorithms are for distilling the generated signatures, and showed that these signatures are practical for real time classification in the real world.

According to author in paper [5], this paper can facilitate collaboration, convergence on standard definitions and procedures. The described Traffic Identification Engine (TIE), an open source tool for network traffic classification, can be applied to both live traffic and previously captured traffic traces. It is also investigated that the performance of multi classification systems when applied to early classification. TIE has the ability to configure from which portion of traffic the features passed to the classifier can be extracted.

The author in paper [7] proposes an unsupervised learning, which is traffic clustering for classification, where labelled training data is difficult and new patterns keep emerging. In order to improve the accuracy of traffic clustering, they constrained clustering schemes, which make decisions by considering some background information are proposed. They use Gaussian mixture density and adapt an appropriate algorithm for estimating the parameters.

III. SYSTEM DESIGN AND METHODOLOGY

The proposed system overcomes the limitation of iterative classifiers. The semi supervised classifiers are using the internet traffic and also overcome the internet bots. The iterative filtering and multi batch seeding is applied to improve the performance. We propose an unsupervised traffic classification that uses both flow features and packet payload. Using a bag-of-words approach and latent semantic analysis, some clusters are identified. Auto-Learning achieves better results in terms of classification performance, provides fine grained visibility on traffic, and offers a simple self-seeding mechanism that naturally allows the system to increase its knowledge. The proposed homogeneous clustering algorithm achieves much better classification performance than existing traffic classification like k-means methods. Homogeneous algorithm improves the overall system performance and resource efficient since traffic reduction is used. The system architecture is as shown in figure.1.

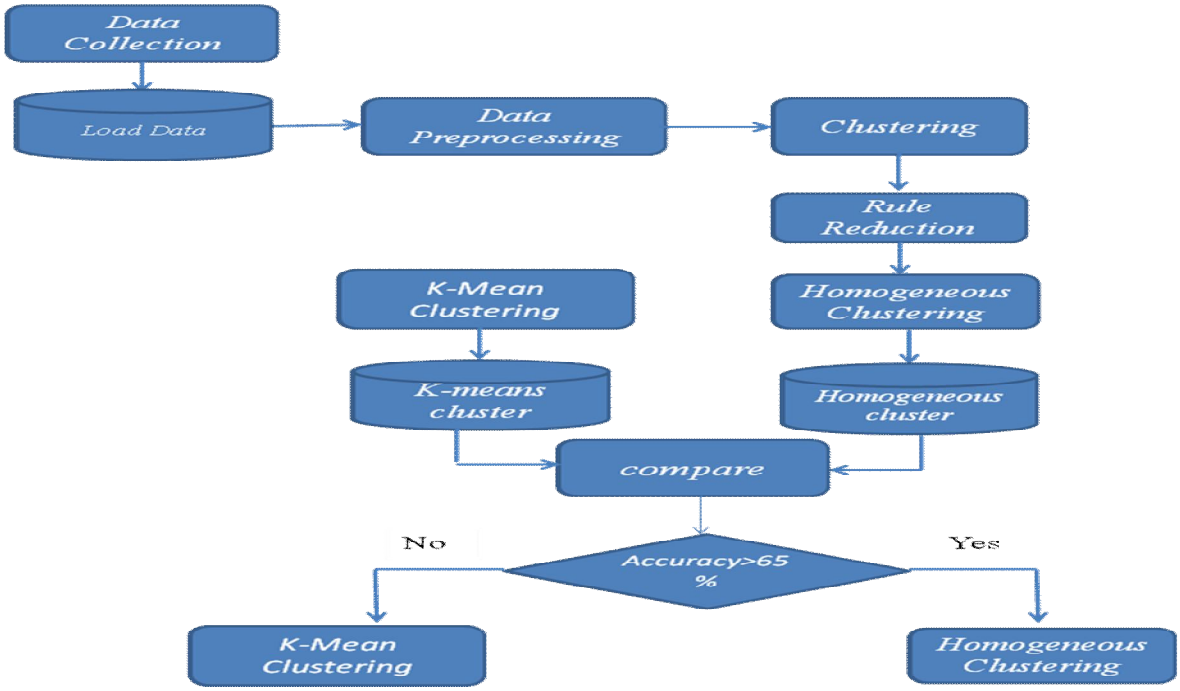

Fig.1 System Architecture

The functionalities of various software modules are explained below which includes four modules namely collection of dataset, data pre-processing, traffic reduction, and feature extraction.

A. Collect Dataset

Most commonly a data set corresponds to the contents of a single database table, or a single statistical data matrix, where every column of the table represents a particular variable, and each row corresponds to a given member of the data set. The data set lists values for each of the variables, such as height and weight of an object, for each member of the data set. Here the Wireshark tool is used to collect the dataset.

B. Data Pre-Processing

Data preparation and filtering steps can take considerable amount of processing time. It includes cleaning, normalization, transformation, feature extraction, and selection etc. Analysing data that has not been carefully screened for such problems can produce misleading results. Thus, the representation and quality of data is first and foremost before running an analysis.

C. Traffic Reduction

Traffic reduction method is one of the filtering method, it can reduce the data needed to be processed and hence increases the overall system performance. However, if a filter eliminates data improperly, bot detection rates could increase. Traffic Reduction can significantly improve the classification performance of many supervised classification algorithms.

D. Feature Extraction

Some of the behavior is distinguishable from normal behavior and hence features of the behavior can be extracted to detect bots. An ideal feature should be applicable to as many bots as possible. The features are collected in the feature extraction stage, like packet size, protocol, server port number, IP addresses etc and then the max membership principle is applied to the features to identify malicious ones. A packet is sent to the feature extraction stage if and only if its source or destination address is listed in the IP address list.

E. Clustering

Clustering is the process of grouping objects with similar features. In this paper the iterative clustering algorithm is used to classify the network traffic. In our work we are going to demonstrate how cluster analysis can be used to effectively identify groups of traffic. We are considering two unsupervised clustering algorithms, namely K-means and iterative homogeneous clustering for

©IJRASET (UGC Approved Journal): All Rights are Reserved

network traffic classification. We evaluate these two algorithms and compare them with the previously used auto class algorithm, using empirical internet traces. Number of parameters used is six and based on these parameters there are three clusters formed with four classes namely FTP, HTTP, Telnet and SMTP. The comparison analysis made between existing K-means algorithm and proposed cluster algorithm. The graph (fig.7) shows the efficiency of proposed algorithm is better than that of existing algorithm. Clustering Algorithm analyses each batch of newly collected flows via the ProcessBatch(). It uses doiterative() function to make pure clusters the below algorithm shows the main loop of proposed algorithm.

This function takes in input

_ *B*, the batch of new flows or dataset;

_ *U*, the set of previous outliers that were not assigned to any class when processing the previous batch;

_ *S*, the set of *seeding flows*, i.e., flows already analysed in past batches for which iterative clustering algorithm was able to provide a label;

As output, it produces

_ *C*, the set of clusters;

_ *NS*, the set of new seeds that are extracted from each cluster;

_ *U*, which contains the set of new outliers;

Its main steps are

1) Clustering the dataset to get homogeneous subsets of flows,

2) Flow label assignment (function doLabeling()), and

3) Extraction of a new set of seeds (function extractSeeds()).Note that flows that are not assigned to any cluster are returned in the *U* set. Those flows are then aggregated in the next batch, so that they can eventually be aggregated to some cluster. In the following it details each step of the batch processing. Steps for malware detection or to detect the internet bots

4) Clustering the dataset to get homogeneous subsets of flows,

5) After homogeneous clustering rule reduction method is used

6) Extraction of a new set of rules (the source and destination address should be present in the IP address list)

7) Comparison between k-means and proposed homogeneous cluster method

IV. EXPERIMENTAL RESULTS

To carry out the experiment we have installed JDK 1.8 on our machine with net beans-IDE. It consists of packet sniffer program to capture and generate a Dataset. The implementation part consists of the following modules namely packet capturing, parameter selection, iterative clustering, labelling and classification.

A. Packet Capturing

This module is mainly used for capturing the packets to classify the traffic. It uses packet sniffer algorithm to capture the packet or packet capturing tools like Wireshark, netflow etc. Here Wireshark tool is used to capture the packet, it is one of the data capturing tools used to provide the structure of different networking protocols. It can also parse and display the fields, along with their meanings as specified by different networking protocols which are shown in the figure .2.

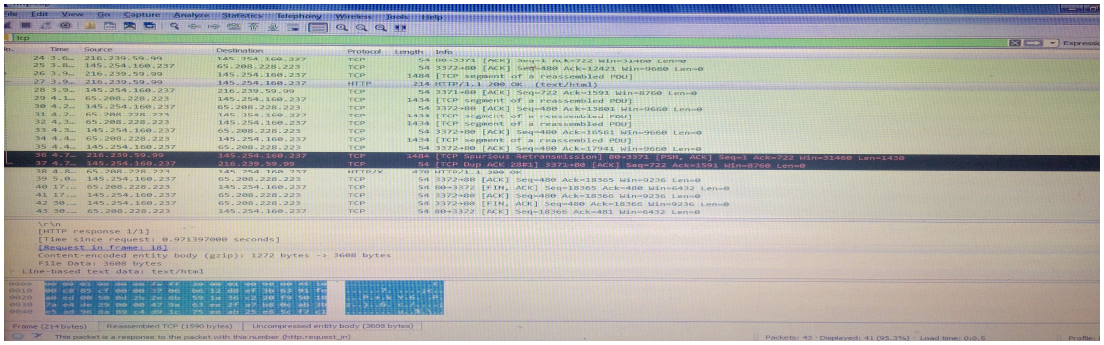

Fig.2. Wireshark Traffic Dump

1) *Tranalyzer2:* Tranalyzer2 is a lightweight flow generator and packet analyzer designed for simplicity, performance and scalability. The program is written in C and built upon the libpcap library. It provides functionality to pre- and post-process

IPv4/IPv6 data into flows and enables a trained user to see anomalies and network defects even in very large datasets, this is shown in figure.3.

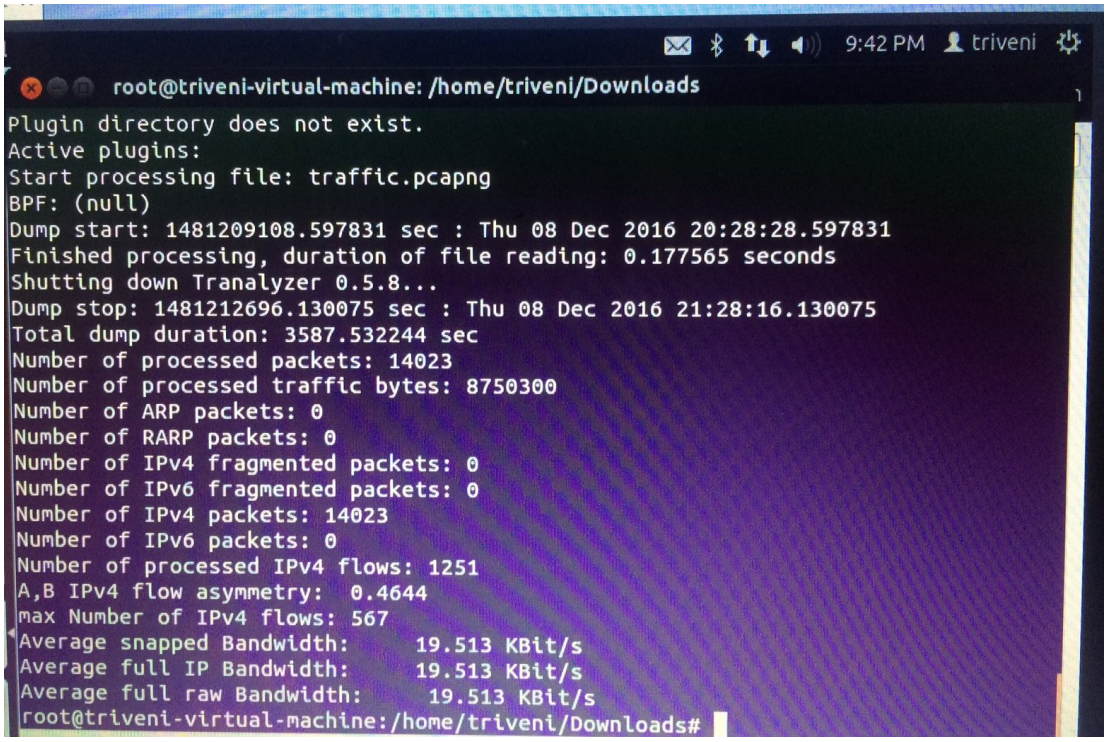

Fig.3. parameter selection using tranlyzer2

2) *Iterative Clustering:* It uses doiterative () function to make pure clusters the below algorithm shows how the iterative clustering will work.
3) *Labelling:* Once flows have been clustered, the doLabeling (C0) procedure assigns a label to each cluster. For each cluster I in C0, flows are checked. If I contains some seeding flows, i.e., flows (extracted from S) that already have a label, a simple majority voting scheme is adopted: the seeding flow label with the largest frequency will be extended to all flows in I, possibly over-ruling a previous label for other seeding flows. More complicated voting schemes may be adopted. The below fig.2 shows the accuracy of the proposed iterative algorithm is more than that of the existing algorithms.

The below snapshots show the results obtained in our work which includes data loading, data pre-processing, clustering and the comparison between existing and proposed system in the form of accuracy.

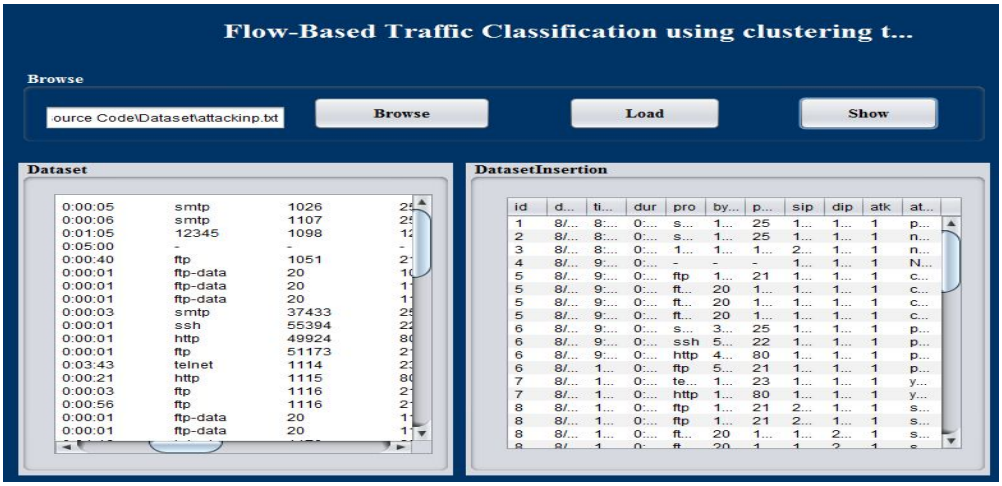

Fig.4 load data

©IJRASET (UGC Approved Journal): All Rights are Reserved

First we need to load the dataset for data pre-processing and for feature extraction which is shown in the fig.2. After loading the data, the data pre-processing phase takes place which is shown in fig.3. It includes cleaning, normalization, transformation, feature extraction, and selection etc

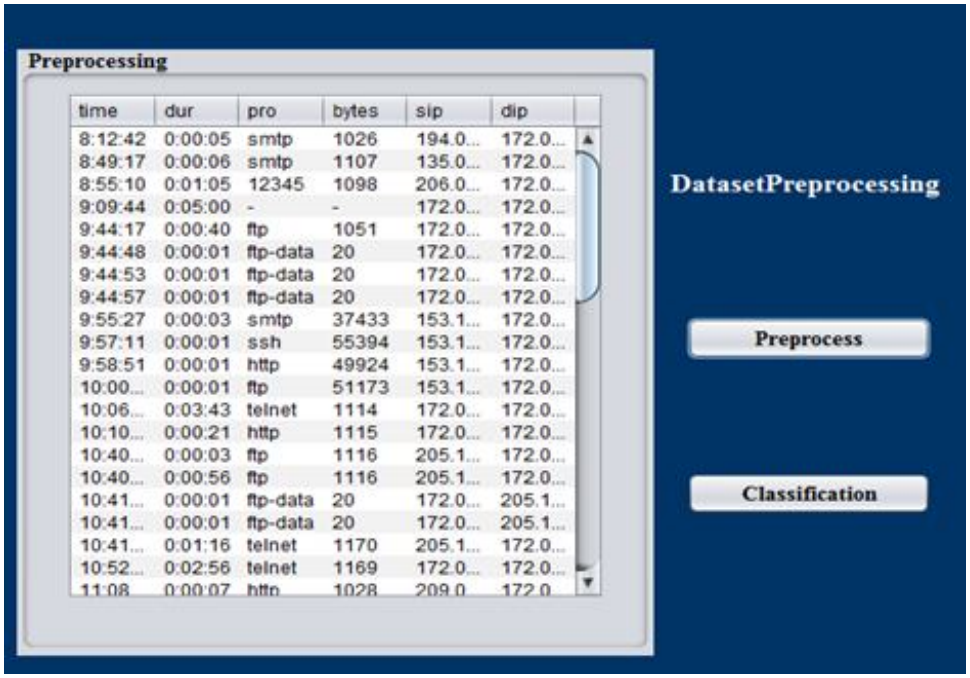

Fig.5 data pre-processing

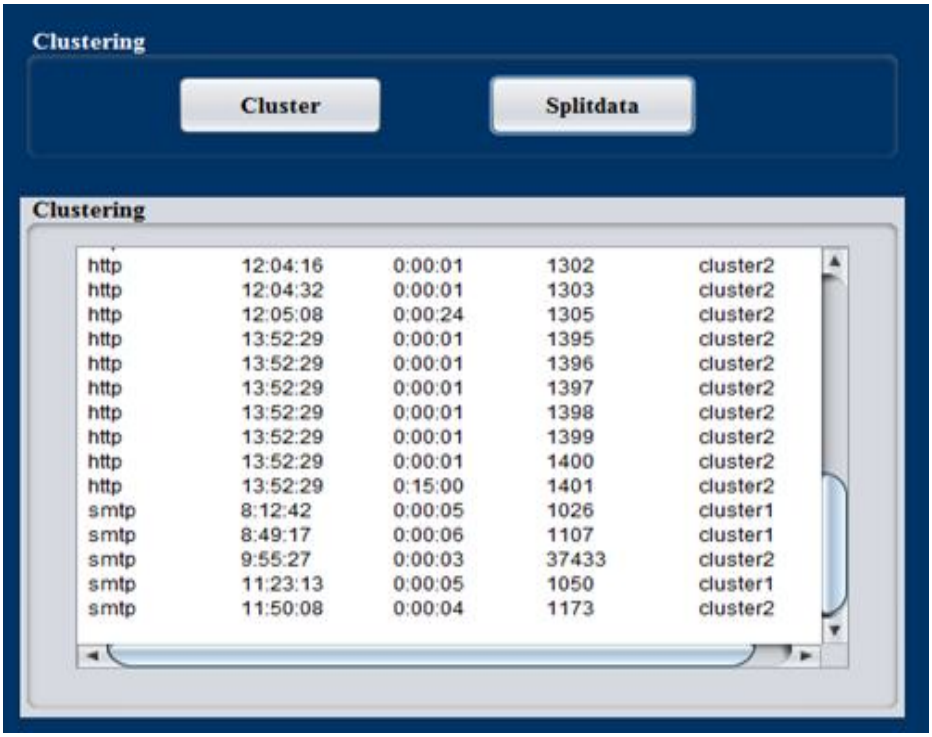

Fig.6 clustering

Cluster process group objects with similar characteristics. Objects are described by means of selected features which are shown in fig.4. In fig.5 shows the comparison between the proposed clustering algorithm and the existing K-means algorithm hence it is concluded that our proposed algorithm is more effective than existing algorithm.

©IJRASET (UGC Approved Journal): All Rights are Reserved

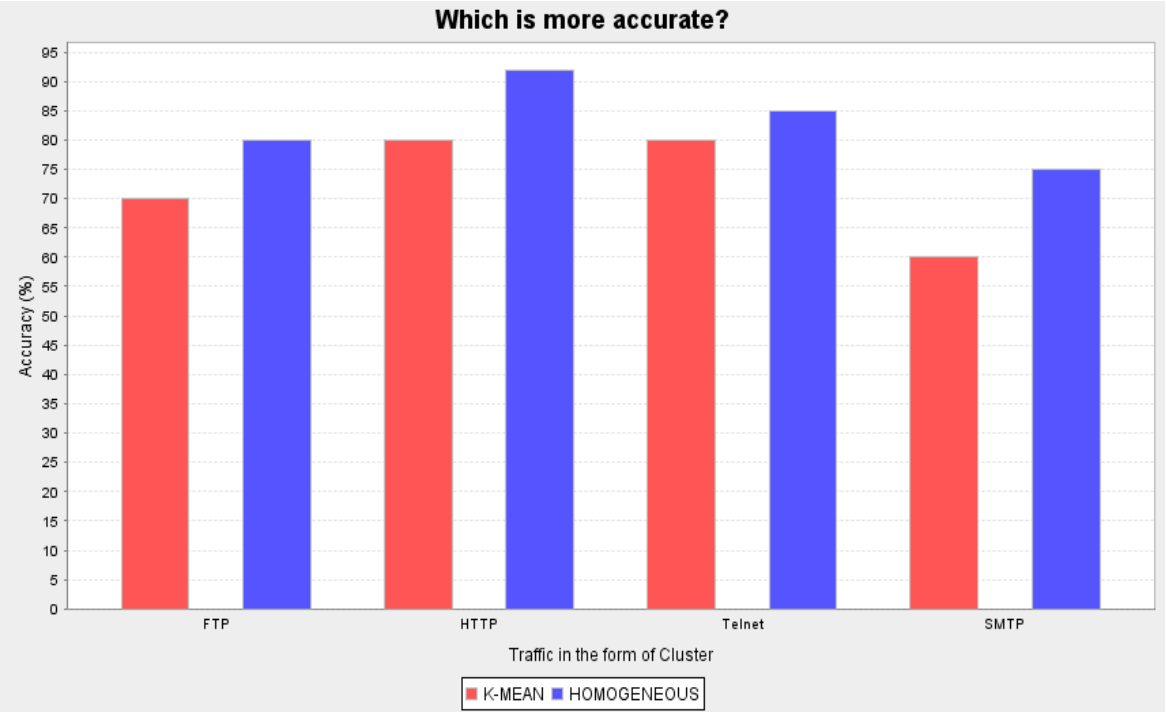

Fig.7 comparison between existing and proposed system

The accuracy graph shown in the figure .7 is the comparison between existing k-means algorithm and proposed clustering algorithm. Here X-axis indicates the generated clusters and Y-axis indicates the accuracy percentage. In this graph there are 4 clusters namely FTP, HTTP, Telnet and SMTP and it shows the percentage values.

V. CONCLUSION

The proposed homogeneous clustering MLA is used for distinguishing different kinds of traffic in a computer network. Here we are focusing on four different applications like FTP, HTTP, Telnet and SMTP. The homogeneous clustering method gives 90% accuracy than the existing k-means method in terms of purity or homogeneity of clusters and it also able to distinguish the traffic which appears to be similar, where an existing system cannot do.

VI. FUTURE SCOPE

The proposed algorithm which is considerably reduces the network traffic. Now the future work will be focusing on providing a good QOS, network security and minimize the network delay
